Preface

This book is a collection of tutorial from the excellent paper by (Wilson et al. 2010). The tutorials have been updated to work with the latest version of the softwares, extended with extra information and other softwares have been added. Eric Postma kindly provided an updated version of the original asreml-r tutorial from asreml-r v3 to asreml-r v4.

This is a living document and information is updated/added regularly

Who are we?

Julien Martin is a Professor at the University of Ottawa working on Evolutionary Ecology and has discovered R with version 1.8.1 and teaches R since v2.4.0. He developed the first version of the book in February 2021 and now continues to develop the book and maintains the site for all languages (currently only english but french and spanish comin soon).

• ****: uOttawa page, lab page

• **Y**: jgamartin

• **(7)**: juliengamartin

Mathieu Videlier is currently a postdoctoral fellow collaborating with Pr. Jacqueline Sztepanacz at University of Toronto. In joined the project in May 2021 . He added and continues to add more details in the document. He is also spearing the translation fo French and Spanish.

Hex Sticker

Chapter 1

Introduction

The book is provides a series of tutorials (and accompanying data files) to fit animal model in R using different packages (ASReml-R, gremlin, MCMCglmm and brms/stan). You will need to carefully follow the instructions below to first download the data files and second install the R packages. Before beginning the tutorial, we assume the reader has successfully installed the chosen R package on their computer and has saved the required data files to an appropriate directory from which they will be read. Full instructions for how to do this are provided with software distributions.

To work though the different tutorial I would recommend to create a folder where you will save your different R scripts for the tutorials.

In addition, the tutorial is here to help researchers in their coding and understanding of models and outputs, but it is required that you read and understand the literature in quantitative genetics and animal model.

1.1. Data

1.1.1. Data files

You will need to download 3 data files for the tutorial in R:

- gryphon.csv: data on gryphon birth weight and morphology
- gryphonRM.csv: data on gryphon repeated measurement of lay date.
- gryphonped.csv: data on the associated pedigree of the data gryphon

In addition, some models presented in the tutorials can take a while to run (sometimes > 1 hour), thus we are also providing the model outputs to allow you continue the tutorial without waiting for the model to run. (But you are free to run models)

The files are available here I recommend to save the data and Rdata files in a subfolder data in the folder you will use as your working directory for R and where you will save your R scripts. It should be noted that the tutorial are using this structure to read or save data.

1.1.2. Notes on data and pedigree

It is always important to take time to think carefully about the strengths and potential limitations of your pedigree information before embarking on quantitative genetic analyses. Pedigree Viewer, written by Brian Kinghorn, is an extremely useful application for visualizing pedigrees, and can be downloaded from: http://www-personal.une.edu.au/~bkinghor/pedigree.htm. Pedantics an R package written by Michael Morrissey and distributed through CRAN (http://cran.r-project.org/) can also be used for this and offers some nice additional features for visualizing pedigree structures and generating associated statistics. Before you begin running through the tutorials, we advise taking a moment to look at the pedigree files provided with them using Pedigree Viewer or Pedantics.

1.2. R

You should check that you have the most current version of R and R packages. You can check the number of the current version on CRAN. If you need to update (or install) R packages, use install.packages() and follow the prompted instructions.

1.2.1. R packages

1.2.1.1. asreml-r

ASReml-R is commercial software published by VSN international (http://www.vsni.co.uk/software/asreml/). This package is not free and requires a key access. Additional information and guide can be find in the Asreml-R manual: (https://asreml.kb.vsni.co.uk/wp-content/uploads/sites/3/2018/02/ASReml-R-Reference-Manual-4.pdf)

1.2.1.2. gremlin

gremlin is a little monster appearing if you feed a mugwai after midnight. It is also a great and promising software written by Pr. Matthew E. Wolak to fit mixed models using a frequentist approach.

1.2.1.3. MCMCglmm

MCMCglmm is an R package for Bayesian mixed model analysis written by Pr. Jarrod Hadfield. It is a freeware distributed through CRAN (http://cran.r-project.org/). Information and guide about the package can be find in the user manual and vignettes (http://cran.r-project.org/web/packages/MCMCglmm/index.html). Reference: (Hadfield 2010).

This module provides some information that applies to MCMCglmm-based analyses in general, but that will not be included in other tutorials. Most importantly, this applies to some of the simplest ways of determining the performance of a run using MCMCglmm, i.e., verification of the validity of of the posterior distribution. This tutorial is not a substitute for working through the MCMCglmm course notes, which is available from CRAN (the Comprehensive R ArchiveNetwork, http://cran.r-project.org/, or can be accessed in R using the command vignette("CourseNotes", "MCMCglmm")). These tutorials do not introduce one of the main advantages of using MCMCglmm for analyses of data from natural populations -the ability to properly model non-normal responses. These capabilities are introduced in the documentation that is distributed with MCMCglmm, and available from CRAN. Another specific animal guide for MCMCglmm can be find (https://devillemereuil.legtux.org/wp-content/up-loads/2021/09/tuto_en.pdf). Pr. Pierre de Villemereuil provide more information in Bayesian concept and focus more on non-gaussian variable.

1.2.1.4. brms

brms provides an interface to fit Bayesian generalized multivariate (non-)linear multilevel models using Stan, which is a C++ package for obtaining full Bayesian inference (see https://mc-stan.org/). The formula syntax is an extended version of the syntax applied in the 'lme4' package to provide a familiar and simple interface for performing regression analyses.

It should be noted that if brms is able to fit animal model the parametrization used is not the most efficient and can take quite longer than using a different parametrization directly in stan.

Part I.

Univariate animal model

This tutorial will demonstrate how to run a univariate animal model to estimate genetic variance in birth weight in the mighty gryphons.

Scenario and data

Scenario

In a population of gryphons there is strong positive selection on birth weight with heavier born individuals having, on average higher fitness. To find out whether increased birth weight will evolve in response to the selection, and if so how quickly, we want to estimate the heritability of birth weight.

Data files

Open gryphonped.csv and gryphon.csv in your text editor. The structure and contents of these files is fairly self-explanatory. The pedigree file gryphonped.csv contains three columns containing unique IDs that correspond to each animal, its father, and its mother. Note that this is a multigenerational pedigree, with the earliest generation (for which parentage information is necessarily missing) at the beginning of the file. For later-born individuals maternal identities are all known but paternity information is incomplete (a common situation in real world applications).

The phenotype data, as well as additional factors and covariates that we may wish to include in our model are contained in gryphon.csv. Columns correspond to individual identity (animal), maternal identity (mother), year of birth (byear), sex (sex, where 1 is female and 2 is male), birth weight (bwt), and tarsus length (tarsus). Each row of the data file contains a record for a different offspring individual. Note that all individuals included in the data file must be included as offspring in the pedigree file.

We can read the data file, using read.csv() which consider by default that NA is the symbol for missing values and that the first line of the file contains the column headers.

It is a good idea to make sure that all variables are correctly assigned as numeric or factors:

```
gryphon$animal <- as.factor(gryphon$animal)
gryphon$mother <- as.factor(gryphon$mother)
gryphon$byear <- as.factor(gryphon$byear)
gryphon$sex <- as.factor(gryphon$sex)
gryphon$bwt <- as.numeric(gryphon$bwt)</pre>
```

```
gryphon$tarsus <- as.numeric(gryphon$tarsus)</pre>
str(gryphon)
'data.frame':
                1084 obs. of 6 variables:
$ animal: Factor w/ 1084 levels "1", "2", "3", "5", ...: 864 1076 549 989 1030 751 987 490 906 591 ...
$ mother: Factor w/ 429 levels "1","2","3","8",..: 362 268 216 375 396 289 328 255 347 240 ...
 $ byear : Factor w/ 34 levels "968","970","971",..: 1 1 2 2 2 2 3 3 3 3 ...
         : Factor w/ 2 levels "1","2": 1 1 2 1 2 1 2 1 1 1 ...
$ bwt
         : num 10.77 9.3 3.98 5.39 12.12 ...
$ tarsus: num 24.8 22.5 12.9 20.5 NA ...
Similarly we can read in the pedigree file, using read.csv() which consider by default that NA is the symbol for
missing values and that the first line of the file contains the column headers.
'data.frame':
                1309 obs. of 3 variables:
$ id
         : int 1306 1304 1298 1293 1290 1288 1284 1283 1282 1278 ...
\ father: int \ NA ...
 $ mother: int NA ...
gryphonped$id <- as.factor(gryphonped$id)</pre>
gryphonped$father <- as.factor(gryphonped$father)</pre>
gryphonped$mother <- as.factor(gryphonped$mother)</pre>
str(gryphonped)
'data.frame':
                1309 obs. of 3 variables:
$ id
         : Factor w/ 1309 levels "1", "2", "3", "4", ...: 1306 1304 1298 1293 1290 1288 1284 1283 1282
```

Now that we have imported the data and the pedigree file, we are ready to fit an animal model.

\$ mother: Factor w/ 429 levels "1","2","3","8",..: NA ...

Chapter 2

Asreml-R

2.0.1. Running the model

First we need to load the asreml library:

```
library(asreml)
```

```
Loading required package: Matrix

Online License checked out Fri Apr 5 15:28:38 2024

Loading ASReml-R version 4.2
```

To be able to fit an animal model, Asreml-r needs (the inverse of) the relationship matrix using the ainverse function:

```
ainv <- ainverse(gryphonped)</pre>
```

We are now ready to specify our first model:

```
model1 <- asreml(
  fixed = bwt ~ 1, random = ~ vm(animal, ainv),
  residual = ~ idv(units),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

ASReml Version 4.2 05/04/2024 15:28:38

	LogLik	Sigma2	DF	wall
1	-4128.454	1.0	853	15:28:38
2	-3284.272	1.0	853	15:28:38
3	-2354.992	1.0	853	15:28:38
4	-1710.357	1.0	853	15:28:38
5	-1363.555	1.0	853	15:28:38
6	-1263.516	1.0	853	15:28:38
7	-1247.854	1.0	853	15:28:38
8	-1247.185	1.0	853	15:28:38
9	-1247.183	1.0	853	15:28:38

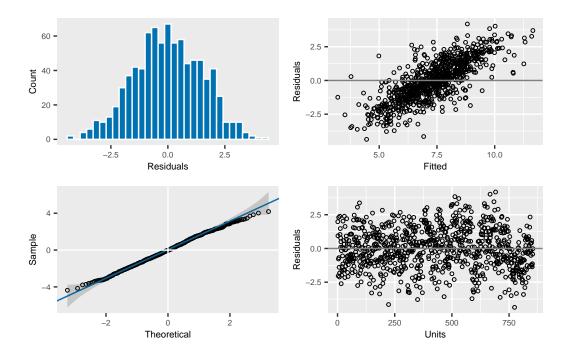

In this model, bwt is the response variable and the only fixed effect is the intercept, denoted as 1. The only random effect we have fitted is animal, which will provide an estimate of V_A . Our random animal effect is connected to the inverse related matrix ainv which integrate the relativeness or pedigree information.

data= specifies the name of the dataframe that contains our variables. Finally, we inform asreml() what to when it encounters NAs in either the dependent or predictor variables (in this case we choose to remove the records). If you use the argument "include" instead of "omit", model will keep the NA. With x="include", the model will exchange NA with 0. Be careful you need to standardize your trait so the mean will be equal to 0, if not estimates (including covariance in multivariate models) could be strongly biased due to the the missing values considered as 0. y="include" will exchange NA with a factor labeled mv which will be included in the sparse equation. For more details see Asreml-R manual.

A note of the specification of the structure of the residuals: This simple univariate model will run fine without residual=~idv(units). However, if you are going to use vpredict() to calculate the heritability (see below), without specifying the residuals in this way will result in a standard error for the heritability that is incorrect.

Any model has assumption which need to be checked. The model can be plot which help visualizing the distribution of the model residual and check the different assumptions.

plot(model1)

To see the estimates for the variance components, we run:

summary(model1)\$varcomp

	${\tt component}$	std.error	z.ratio	bound	%ch
<pre>vm(animal, ainv)</pre>	3.395398	0.6349915	5.347154	P	0
units!units	3.828602	0.5185919	7.382687	P	0
units!R	1.000000	NA	NA	F	0

We fitted a single random effect so we partitioned the phenotypic variance into two components. The vm(animal, ainv) variance component is V_A and is estimated as 3.4. Given that the ratio of V_A to its standard error (z.ratio) is considerably larger than 2 (i.e. the parameter estimate is more than 2 SEs from zero), this looks likely to be significant. The units!units component refers to the residual variance V_R , and units\$R should be ignored. If you don't include residual=~idv(units) in your model specification, units\$R will provide you with the residual variance.

2.0.2. Estimating heritability

We can calculate the h^2 of birth weight from the components above since $h^2 = V_A/V_P = V_A/(V_A + V_R)$. Thus according to this model, $h^2 = 3.4 / (3.4 + 3.83) = 0.47$.

Alternatively we can use the vpredict() function to calculate h^2 and its standard error. vpredict() function has two structures, first the model used (here model1) and then the estimate name with its associated equation. The equation used different V and their associated numbers depend of the order of the different random and residual effects included in the model.

```
vpredict(model1, h2.bwt ~ V1 / (V1 + V2))
```

Estimate SE

h2.bwt 0.4700163 0.07650881

2.0.3. Adding fixed effects

To add fixed effects to a univariate model, we simply modify the model statement. For example, we might know (or suspect) that birth weight is a sexually dimorphic trait and therefore fit in the model.

```
model2 <- asreml(
  fixed = bwt ~ 1 + sex,
  random = ~ vm(animal, ainv),
  residual = ~ idv(units),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

ASReml Version 4.2 05/04/2024 15:28:40

	LogLik	Sigma2	DF	wall
1	-3364.126	1.0	852	15:28:40
2	-2702.117	1.0	852	15:28:40
3	-1978.916	1.0	852	15:28:40
4	-1487.834	1.0	852	15:28:40
5	-1236.350	1.0	852	15:28:40
6	-1172.771	1.0	852	15:28:40
7	-1165.270	1.0	852	15:28:40
8	-1165.093	1.0	852	15:28:40
9	-1165.093	1.0	852	15:28:40

Now we can look at the fixed effects parameters and assess their significance with a conditional Wald F-test:

solution std error z.ratio
(Intercept) 6.058669 0.1718244 35.26082
sex_1 0.000000 NA NA
sex_2 2.206996 0.1619974 13.62365

ASReml Version 4.2 05/04/2024 15:28:40

	LogLik	Sigma2	DF	wall
1	-1165.093	1.0	852	15:28:40
2	-1165.093	1.0	852	15:28:40

\$Wald

Df denDF F.inc F.con Margin Pr
(Intercept) 1 251 3491.0 3491.0 0
sex 1 831 185.6 185.6 A 0

\$stratumVariances

df Variance vm(animal, ainv) units!units
vm(animal, ainv) 752.28476 5.957254 0.9864077 1
units!units 99.71524 2.938413 0.0000000 1

The very small probability (Pr) in the Wald test above shows that sex is a highly significant fixed effect, and from the parameter estimates (summary(model2,coef=T)\$coef.fixed) we can see that the average male (sex 2) is 2.2 kg (\pm 0.16 SE) heavier than the average female (sex 1). However, when we look at the variance components in the model including sex as a fixed effect, we see that they have changed slightly from the previous model:

summary(model2)\$varcomp

component std.error z.ratio bound %ch vm(animal, ainv) 3.060441 0.5243571 5.836558 P 0 units!units 2.938412 0.4161473 7.060991 P 0 units!R 1.000000 NA NA F 0

In fact since sex effects were previously contributing to the residual variance of the model, our estimate of V_R (denoted units!R in the output) is now slightly lower than before. This has an important consequence for estimating heritability since if we calculate V_P as V_A+V_R then as we include fixed effects we will soak up more residual variance driving V_P . Assuming that V_A is more or less unaffected by the fixed effects fitted then as V_P goes down we expect our estimate of h^2 will go up:

```
(h2.1 <- vpredict(model1, h2.bwt ~ V1 / (V1 + V2)))

Estimate     SE
h2.bwt 0.4700163 0.07650881

(h2.2 <- vpredict(model2, h2.bwt ~ V1 / (V1 + V2)))

Estimate     SE</pre>
```

Here h^2 has increased slightly from 0.47 to 0.51. Which is the better estimate? It depends on what your question is. The first is an estimate of the proportion of variance in birth weight explained by additive effects, the latter is an estimate of the proportion of variance in birth weight *after conditioning on sex* that is explained by additive effects.

An important piece of advice, each researcher should be consistent in how they name their estimates and always correctly describe which estimates they are using conditional or not (to avoid any confusion).

2.0.4. Adding random effects

h2.bwt 0.510171 0.07432388

This is done by simply modifying the model statement in the same way. For instance fitting:

```
model3 <- asreml(
  fixed = bwt ~ 1 + sex,
  random = ~ vm(animal, ainv) + byear,
  residual = ~ idv(units),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

ASReml Version 4.2 05/04/2024 15:28:40

	LogLik	Sigma2	DF	wall
1	-2742.658	1.0	852	15:28:40
2	-2237.268	1.0	852	15:28:40
3	-1690.453	1.0	852	15:28:40
4	-1328.910	1.0	852	15:28:40
5	-1154.597	1.0	852	15:28:40
6	-1116.992	1.0	852	15:28:40
7	-1113.809	1.0	852	15:28:40
8	-1113.772	1.0	852	15:28:40
9	-1113.772	1.0	852	15:28:40

summary(model3)\$varcomp

	component	std.error	z.ratio	bound	%ch
byear	0.8862604	0.2695918	3.287416	P	0
<pre>vm(animal, ainv)</pre>	2.7068665	0.4422140	6.121169	P	0
units!units	2.3092415	0.3451025	6.691466	P	0
units!R	1.0000000	NA	NA	F	0

Estimate SE

h2.bwt 0.4586068 0.06740364

Here the variance in bwt explained by byear is 0.89 and, based on the z.ratio, appears to be significant (>2). Thus we would conclude that year-to-year variation (e.g., in weather, resource abundance) contributes to V_P . Note that although V_A has changed somewhat, as most of what is now partitioned as a birth year effect was previously partitioned as V_R . Thus what we have really done here is to partition environmental effects into those arising from year-to-year differences versus everything else, and we do not really expect much change in h^2 (since now $h^2 = V_A/(V_A + V_{BY} + V_R)$).

However, we get a somewhat different result if we also add a random effect of mother to test for maternal effects:

```
model4 <- asreml(
  fixed = bwt ~ 1 + sex,
  random = ~ vm(animal, ainv) + byear + mother,
  residual = ~ idv(units),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

Here partitioning of significant maternal variance has resulted in a further decrease in V_R but also a decrease in V_A . The latter is because maternal effects of the sort we simulated (fixed differences between mothers) will have the consequence of increasing similarity among maternal siblings. Consequently they can look very much like additive genetic effects and if present, but unmodelled, represent a type of "common environment effect" that can - and will - cause upward bias in V_A and so h^2 . The "common environment" can be conceived as the inextricable sum of the maternal additive genetic effect (such as maternal loci) and the maternal environment or permanent environment (such as litter or nest environment created or modified by the mother).

2.0.5. Testing significance of random effects

An important point to note in this tutorial is that while the z.ratio (component/std.error) reported is a good indicator of likely statistical significance (>1.96?), the standard errors are approximate and are not recommended for formal hypothesis testing. A better approach is to use likelihood-ratio tests (LRT).

For example, to test the significance of maternal effects we could compare models with and without the inclusion of maternal identity as a random effect and compare the final log-likelihoods of these models.

model4\$loglik

[1] -1094.815

shows that the model including maternal identity has a log-likelihood of -1094.815, and

model3\$loglik

[1] -1113.772

shows that the model excluding maternal identity has a log-likelihood of -1113.772.

A test statistic equal to twice the absolute difference in these log-likelihoods is assumed to be distributed as Chi square with one degree of freedom (one term of difference between the two models). In this case we would conclude that the maternal effects are highly significant since: $2 \times (-1094.8145793 - -1113.7719147)$ equals 37.9146708, and the p-value that comes with this is:

[1] 7.390738e-10

```
1 - pchisq(2 * (model4$loglik - model3$loglik), 1)
```

As P < 0.0001 we would therefore conclude that the additional of maternal identity as a random effect significantly improves the fit of the model, given an increase in log-likelihood of approximately 19.

2.0.6. Further partitioning the variance

A population can be further fragmented into different groups or categories (such as females and males, juveniles and adults or treated and untreated). Some scientific questions require further and deeper analysis of the variance. To avoid multiple model (one for each group), we can directly partition the variance between groups in a unique model. In addition, by doing so, we can also test if the variance are different between groups.

As example, we decide to take the model4 and partition its additive genetic variance and residual variance by sex. It is possible to further partition the other random effects but it will complexity the animal model and requires sufficient sample size.

First, it required to order the dataset by group (here sex).

```
gryphon <- gryphon[order(gryphon$sex), ]</pre>
```

To partition variances between sex, two distinct functions are require at() for the random level, and dsum() for the residual level:

```
model_SEX <- asreml(
  fixed = bwt ~ 1 + sex,
  random = ~ at(sex):vm(animal, ainv) + byear + mother,
  residual = ~ dsum(~ units | sex),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

```

By partitioning the additive genetic variance and the residual variance, the model estimates the V_A and V_R for each group (sex). Doing so, we can calculate the h^2 for each group of sex. Here, it's important to know in which order the variances are estimated to extract the correct variance in the heritability equation.

```
(h2.F <- vpredict(model_SEX, h2.bwt ~ V3 / (V1 + V2 + V3 + V5)))
```

Estimate SE

h2.bwt 0.2457811 0.1070794

```
(h2.M <- vpredict(model_SEX, h2.bwt ~ V4 / (V1 + V2 + V4 + V6)))
```

Estimate SE

h2.bwt 0.3345244 0.1619218

To test if the variances are different between sexes, we can compare the model partitioned model_SEX and the previous model without the partitioning model4 in a likelihood ratio test (LRT) with 2 degrees of freedom since models have two components of variance of difference.

```
model_SEX$loglik
```

[1] -1104.364

model4\$loglik

[1] -1094.815

```
1 - pchisq(2 * (model_SEX$loglik - model4$loglik), 2)
```

[1] 1

Here, we can see the point estimates of h^2 seems to differ between sexes (0.25 and 0.33), but their SE overlaps. LRT give more information and showed that partitioning the variance and the residual between sexes did not improved the fit of the model and so their variance are not significantly different.

```
h2.sex <- rbind(h2.F, h2.M)

plot(c(0.95, 1.05) ~ h2.sex[, 1], xlim = c(0, 0.8), ylim = c(0.5, 1.5), , xlab = "", ylab = "", carrows(y0 = 0.95, x0 = h2.sex[1, 1] - h2.sex[1, 2], y1 = 0.95, x1 = h2.sex[1, 1] + h2.sex[1, 2], arrows(y0 = 1.05, x0 = h2.sex[2, 1] - h2.sex[2, 2], y1 = 1.05, x1 = h2.sex[2, 1] + h2.sex[2, 2], mtext("Narrow-sense heritability (±se)", side = 1, las = 1, adj = 0.4, line = 3, cex = 1.6)

axis(2, at = 1, labels = c("birth weight"), las = 3, cex.axis = 1.6)
```

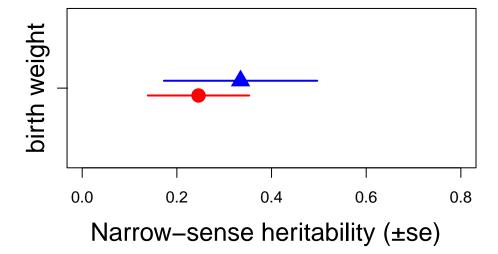

Figure 2.1.: Female and male heritability of birth weight

2.0.7. Modification of the varaince matrix parameters

Variance represents the deviation of the distribution and it expected to be a positive values. Due to a lack of power, a structural problem in the dataset or a very low variance, Asreml-r often fixes the variance to a boundary B instead of a positive value P. When it is happen, it is generally a good idea to examine it.

To examine the boundary effect, we can explore an alternative model where the model allowed a unstructured parameter for the variance of interest or the entire variance matrix. For this example: we allowed the model to estimate any values (so allowing possible negative values of estimates) for the random and residual matrix.

First, we create a temporary model model.temp with the exact structure to modify.

```
model.temp <- asreml(
    fixed = bwt ~ 1,
    random = ~ vm(animal, ainv) + byear + mother,
    residual = ~ idv(units),
    data = gryphon,
    na.action = na.method(x = "omit", y = "omit"),
    start.values = T
)
G.temp <- model.temp$vparameters[(1:3), ]
G.temp$Constraint <- "U"
R.temp$Constraint[2] <- "U"</pre>
```

The argument start.values=T allowed the model.temp to change its random parameters. We can create the two different matrices and specify which parameters will be modified. For this example we modified the G and the R matrix to fit all variance to be U unstructured. it is important to note for the R matrix the line units!R has to be fix to 1, so it will never change.

The object G.temp and R.temp can be implemented in the following model as new parameters using the argument R.param and G.param.

```
model5 <- asreml(
  fixed = bwt ~ 1 + sex,
  random = ~ vm(animal, ainv) + byear + mother,</pre>
```

```
residual = ~ idv(units),
data = gryphon,
na.action = na.method(x = "omit", y = "omit"),
R.param = R.temp, G.param = G.temp
)
```

Since model4 did not showed boundary, the model5 is very similar.

2.0.8. Covariance between two random effects

Some research questions require to estimate the covariance between two random effects within a univariate model. To do so, we can use the argument str. As an example, we fit a model which estimate the covariance between the additive genetic variance and the mother variance. Both variances require to operate on the same level, thus animal and mother require to be associated to the pedigree information.

The argument strhas two components: first the equation term with the two random effects ~vm(animal,Ainv)+vm(mother, ainv) and second the structural term ~us(2):id(number). Here within the structural term, we fit a 2x2 unstructured matrix us(2) which estimated the variance and the covariance between the random effects in the equation term. To successfully work, the structural term also requires the number of level identified within id(). Here a small tip, if you don't know the number of level identified within id(), run the model with a random number. The model will not converge and a error message will appear like this one: Size of direct product (4) does not conform with total size of included terms (2618). The error message can help you determine the required level within the str function, as here 2618 divide by 2. In addition, it is necessary the random effects

```
model.temp2 <- asreml(</pre>
  fixed = bwt ~ 1,
  random = ~ str(~ vm(animal, ainv) + vm(mother, ainv), ~ us(2):id(1309)) + byear,
  residual = ~ idv(units),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit"),
  start.values = T
)
G.temp2 <- model.temp2$vparameters[(1:4), ]</pre>
G.temp2$Constraint <- "U"</pre>
model6 <- asreml(</pre>
  fixed = bwt \sim 1 + sex,
  random = ~ str(~ vm(animal, ainv) + vm(mother, ainv), ~ us(2):id(1309)) + byear,
  residual = ~ idv(units),
  data = gryphon,
  na.action = na.method(x = "omit", y = "omit"),
  # equate.levels = c("animal", "mother"),
  , G.param = G.temp2
)
summary(model6)$varcomp
```

We have successfully produced a code to estimate the covariance between two random effects. However for this example, the dataset is not sufficient to properly estimate it and the model did not converge but you have the idea of how to use the function str.

Additional and final tip: It is happen that Asreml will estimate negative variance if you allow the variance matrix to be unstructured. A negative variance is counter-intuitive meaning statistically the mean within the random effect is less similar than expected by chance. However a possible biological reason can be hypothesized such as a sibling competition within the nest creating a negative among-individual covariance within the nest. Thus to test this hypotheses, it is required to estimate the covariance between two random effects.

Chapter 3

MCMCglmm

3.0.1. Running the model

First load MCMCglmm:

```
library(MCMCglmm)
```

Loading required package: Matrix

Loading required package: coda

Loading required package: ape

The first model we will fit is a simple animal model with no fixed effects, and only an 'animal' random effect relating individuals to their additive genetic values through the pedigree.

First we are going to define the priors. In a way we might want to avoid using priors, because we would like all of the information in our analysis to come from our data. By default MCMCglmm uses improper priors, but this can cause inferential and numerical problems. We will specify priors for the animal effect and the residual variance using the following code:

```
prior1.1 <- list(
   G = list(G1 = list(V = 1, nu = 0.002)),
   R = list(V = 1, nu = 0.002)
)</pre>
```

A prior allowed the model to fit different variance structures. With the unique random effect "animal", we partitioned the phenotypic variance into two distinct variances matrices G (additive genetic) and R (residual). This prior specification is the simplistic one and often used because it was believed to be relatively uninformative, and is equivalent to an inverse-gamma prior with shape and scale equal to 0.001. In many cases it is relatively uninformative but when the posterior distribution for the variances has support close to zero it can behave poorly. Parameter expanded priors (See Chapter 8 of the MCMCglmm CourseNotes, available from CRAN) are gaining in popularity due to their better behaviour but for the purposes of this tutorial we will stick with the inverse-gamma prior.

We have told MCMCglmm to pay little heed to our prior expectation (V) by specifying a small degree of belief parameter (nu) of 0.002. Since this is a univariate analysis, the priors are matrix of order 1 and thus nu>0 is the smallest degree of belief that provides what is known as a 'proper' prior, avoiding numerical problems. In fact, there is a lot of information in the data regarding the marginal distributions of the parameters, and MCMCglmm will run most of the models that we suggest in these tutorials without priors. However, this is poor practice, but we will therefore use this simple priors throughout these tutorials. We can now fit an animal model. The model to decompose variation in birth weight into genetic and residual effects is as follows:

The lower case "animal" is a can be a **special** word for MCMCglmm. If a pedigree argument is provided then MCMCglmm will recognize the term animal as the term to use to estimate additive genetic variance. When the argument pedigree is not provided then the word animal is not different than any other variable. However, instead of providing a pedigree argument to the call to MCMCglmm function, it is much more flexible to use the ginv argument to specify the random effect that must be linked to the pedigree (with the inverse relatedness matrix). We thus first estimate the inverse relatedness matrix using inverseA() then fit the animal model.

```
Ainv <- inverseA(gryphonped)$Ainv
model1.1 <- MCMCglmm(bwt ~ 1,
   random = ~animal, ginv = list(animal = Ainv),
   data = gryphon, prior = prior1.1
)</pre>
```

```
MCMC iteration = 0

MCMC iteration = 1000

MCMC iteration = 2000
```

MCMC iteration = 3000

MCMC iteration = 4000

MCMC iteration = 5000

MCMC iteration = 6000

MCMC iteration = 7000

MCMC iteration = 8000

MCMC iteration = 9000

MCMC iteration = 10000

MCMC iteration = 11000

MCMC iteration = 12000

MCMC iteration = 13000

After typing this code, MCMCglmm will run, taking about 20 seconds on a modern desktop computer. The progress of the run will be printed to the screen. Also, note the warning message will be printed at the end of the run. This is natural too. In order for the MCMC algorithm to work, MCMCglmm must keep track of effects associated with unmeasured individuals appearing in the pedigree. This will not affect the answers, but when many unmeasured individuals exist, it can hinder the ability of the algorithm to explore the parameter space (more on this, and a solution, later). Lets have a look at the MCMCglmm outputs. First we will evaluate how confident we can be that MCMCglmm found good answers. By entering

plot(model1.1\$Sol)

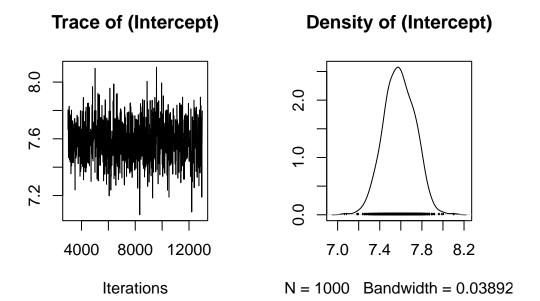

Figure 3.1.: The posterior distribution of the fixed effect (the intercept, or mean) in model 1.1

in the console, we get Figure 2.2. The plot on the left shows a time series of the values of 1000 samples of the posterior distribution of the the model intercept (mean birth weight). The plot on the right shows the same data as a distribution. Complicated statistical methods for estimating population means are of course of little interest; rather, we are examining these outputs to check that MCMCglmm's algorithms worked well for our data and for this model. The important point here is that a consistent amount of variation around a largely unchanging mean value of the intercept was obtained (which give this fluctuating trace concentrated around the mean), and the posterior distribution of the intercept appears to be valid. More rigorous means of evaluation the independence of the samples in the posterior distribution (evaluating autocorrelation) are discussed in the MCMCglmm CourseNotes, available from CRAN. Note that your output for model 1.1 may not be identical to this due to Monte Carlo (random number) error. So every times, you run the model, you will get similar but slightly different results.

The posterior distributions of the the variance components are generally of more interest to animal model users. We can view plots of the posterior distribution for the variance components for model 1.1 by

plot(model1.1\$VCV)

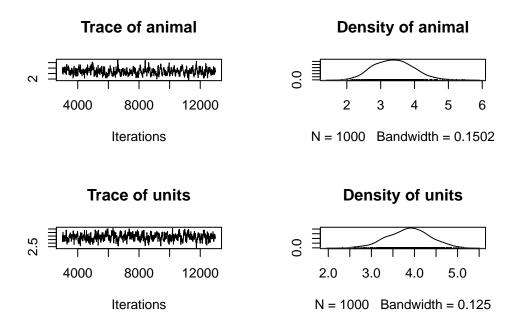

Figure 3.2.: The posterior distributions of the variance components of model 1.1, based on an analysis with the default values for nitt, burnin, and thin in MCMCglmm

which generates Figure 2.3. Here we see distributions of the estimates of the additive genetic (animal) and residual (units) effects. These samples contain some autocorrelation, i.e., trends are apparent in the left-hand plot. We can deal with this easily.

3.0.2. Change in iteration and sampling

We will simply re-run the model for a longer number of iterations, and sample the chain less frequently. So far we have been running MCMCglmm with its default values. These defaults are a total run length of 13000 iterations, the first 3000 of which are discarded as a 'burn-in' period to make sure that the converges to the part of the parameter space where the maximum likelihood exists. The remaining 10000 iterations are sampled (estimates retained) every 10 iterations (the thinning interval). Because the values in the left-hand plots in figure 2.2 to appear to have different values at the beginning of the run, we might suspect that a longer burn-in period might be required. We can reduce the autocorrelation by lengthening the rest of the run and sampling the chain less frequently. The following code runs the same model 1.1, but is likely to produce better samples of the posterior distributions. This model should take about two minutes to analyze.

```
model1.1 <- MCMCglmm(bwt ~ 1,
  random = ~animal, ginv = list(animal = Ainv),
  data = gryphon, nitt = 65000, thin = 50, burnin = 15000,</pre>
```

```
prior = prior1.1, verbose = FALSE
)
```

Notes that we have now included the argument verbose=FALSE in the MCMCglmm call. We will continue this throughout the tutorial so that more complete screen outputs can be included in this document without using too much space. Note that the autocorrelation is much reduced. A more compact way to evaluate the validity of the posterior distributions is to calculate autocorrelation among samples, as follows:

```
autocorr.diag(model1.1$VCV)
```

```
animal units
Lag 0 1.00000000 1.00000000
Lag 50 0.22557278 0.18432336
Lag 250 0.04529195 0.05833619
Lag 500 0.02911877 0.02162644
Lag 2500 0.04993585 0.04805583
```

We will consider these levels of autocorrelation acceptable, at least for the purposes of this tutorial. Ideally, all samples of the posterior distribution should be independent, and the autocorrelation for all lag values greater than zero should be near zero. However, in practice this will not strictly be achievable for all analytic scenarios. Certainly the levels of autocorrelation observed here should not be tolerated in any formal analysis. Note that the validity of posterior distributions of any analysis should always be checked; however, for brevity we will not continue to be so consistently diligent throughout the rest of these tutorials. We can now proceed with confidence to recover some more information from these samples. We can obtain estimates of the additive genetic and residual variance by calculating the modes of the posterior distributions:

```
posterior.mode(model1.1$VCV)
```

```
animal units 3.624195 3.976344
```

We can obtain the Bayesian equivalent of confidence intervals by calculating the the values of the estimates that bound 95% (or any other proportion) of the posterior distributions:

HPDinterval(model1.1\$VCV)

```
lower upper
animal 2.076880 4.604824
units 2.798573 4.881532
attr(,"Probability")
```

3.0.3. Change priors parameters

We specified weak priors in this analyses. Now we will check whether or not proper priors would have influenced the results that we obtained. The simplest way to do this is to re-run the model with different priors. In the previous model we specified a prior where the size of genetic and residual variance were similar. Here we construct priors with a larger degree of belief parameter (nu), and we will specify that a large proportion (95%) of the variation is under genetic control (V). Thus, the residual variance contains 05% of the phenotypic variance.

```
p.var <- var(gryphon$bwt, na.rm = TRUE)
prior1.1.2 <- list(
   G = list(G1 = list(V = matrix(p.var * 0.95), nu = 1)),
   R = list(V = matrix(p.var * 0.05), nu = 1)
)

model1.1.2 <- MCMCglmm(bwt ~ 1,
   random = ~animal, ginv = list(animal = Ainv),
   data = gryphon, prior = prior1.1.2, nitt = 65000, thin = 50,
   burnin = 15000, verbose = FALSE
)

posterior.mode(model1.1$VCV)</pre>
```

```
animal units 3.624195 3.976344
```

```
posterior.mode(model1.1.2$VCV)

animal units
3.411235 3.869403
```

and we can therefore conclude that the difference in the priors has little effect on the outcome of the analysis. This is typical for an analysis where lots of data are available relative to the complexity of the model, but is often not the case. In all cases, it is important to check the effect of priors on conclusions drawn from a model. In addition, you can also specify the prior with previous knowledge or expectation for the variance.

3.0.4. Estimating heritability

A useful property of Bayesian posterior distributions is that we can apply almost any transformation to these distributions and they will remain valid. This applies to the calculation of heritability. We can obtain an estimate of the heritability by applying the basic formula $h^2 = V_A/V_P$ to each sample of the posterior distribution:

```
posterior.heritability1.1 <- model1.1$VCV[, "animal"] /
   (model1.1$VCV[, "animal"] + model1.1$VCV[, "units"])

posterior.mode(posterior.heritability1.1)</pre>
```

var1 0.466366

```

Generate a plot of the posterior distribution of this heritability estimate:

plot(posterior.heritability1.1)

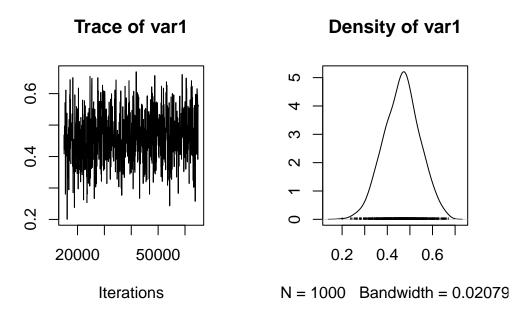

Figure 3.3.: The posterior distributions the heritability from model 1.1

3.0.5. Adding fixed effects

To add effects to a univariate model, we simply modify the fixed effect part of the model specification:

```
model1.2 <- MCMCglmm(bwt ~ sex,
    random = ~animal, ginv = list(animal = Ainv),
    data = gryphon, prior = prior1.1,
    nitt = 65000, thin = 50, burnin = 15000, verbose = FALSE
)
summary(model1.2)</pre>
```

```
Iterations = 15001:64951
Thinning interval = 50
Sample size = 1000
DIC: 3717.49
G-structure: ~animal
```

[1] 0.95

```
post.mean 1-95% CI u-95% CI eff.samp
animal
           3.068
                     2.13
                               4.13
                                       691.8
R-structure:
               ~units

                                   2.528
                                           1000.0 < 0.001 ***
                0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

We can assess the significance of sex as a fixed effect by examining its posterior distribution. Important notes here, it is important to know how the model names their fixed effect level to call them properly.

```
posterior.mode(model1.2$Sol[, "sex2"])

    var1
2.260058

HPDinterval(model1.2$Sol[, "sex2"], 0.95)

    lower upper
var1 1.89983 2.527696
attr(,"Probability")
```

The posterior distribution of the sex2 term does not overlap zero. Thus, we can infer that sex has an effect on birth weight (presence of a sexual dimorphism) in this model and is a useful addition to the model, for most purposes. It is also worth noting that the variance components have changed slightly:

```
posterior.mode(model1.2$VCV)
```

```
animal units 3.099095 3.134758
```

In fact since sex effects were previously contributing to the residual variance of the model our estimate of V_R (denoted 'units' in the output) is now slightly lower than before. This has an important consequence for estimating heritability since if we calculate V_P as $V_A + V_R$ then as we include fixed effects we will soak up more residual variance driving V_P . Assuming that V_A is more or less unaffected by the fixed effects fitted then as V_P goes down we expect our estimate of h^2 will go up.

```
posterior.heritability1.2 <- model1.2$VCV[, "animal"] /
   (model1.2$VCV[, "animal"] + model1.2$VCV[, "units"])
posterior.mode(posterior.heritability1.2)</pre>
```

var1

0.5140724

```
HPDinterval(posterior.heritability1.2, 0.95)
```

```
lower upper var1 0.350474 0.6389083 attr(,"Probability")
[1] 0.95
```

Here h^2 has increased slightly from 0.4829 to 0.5079 (again, your values may differ slightly due to Monte Carlo error). Which is the better estimate? It depends on what your question is. The first is an estimate of the proportion of variance in birth weight explained by additive effects, the latter is an estimate of the proportion of variance in birth weight after conditioning on sex that is explained by additive effects. An important piece of advice, each researcher should be consistent in how they name their estimates and always correctly describe which estimates they are using conditional or not (to avoid any confusion).

3.0.6. Adding random effects

This is done by simply modifying the model statement in the same way, but requires addition of a prior for the new random effect. For instance, we can fit an effect of birth year:

```
prior1.3 <- list(
   G = list(G1 = list(V = 1, nu = 0.002), G2 = list(V = 1, nu = 0.002)),
   R = list(V = 1, nu = 0.002)
)

model1.3 <- MCMCglmm(bwt ~ sex,
   random = ~ animal + byear, ginv = list(animal = Ainv),
   data = gryphon,
   nitt = 65000, thin = 50, burnin = 15000,
   prior = prior1.3, verbose = FALSE
)

posterior.mode(model1.3$VCV)</pre>
```

```
animal byear units 2.5316830 0.9198862 2.2776450
```

Here the variance in birth weight explained by birth year is 0.92. Note that although V_A has changed somewhat, most of what is now partitioned as a birth year effect was previously partitioned as V_R . Thus what we have really done here is to partition environmental effects into those arising from year to year differences versus everything else, and we do not really expect much change in h^2 (since now $h^2 = V_A/(V_A + V_{BY} + V_R)$). However, we get a somewhat different result if we also add a random effect of mother to test for maternal effects:

```
prior1.4 <- list(
    G = list(
    G1 = list(V = 1, nu = 0.002),
    G2 = list(V = 1, nu = 0.002),
    G3 = list(V = 1, nu = 0.002)
),</pre>
```

```
R = list(V = 1, nu = 0.002)
)

model1.4 <- MCMCglmm(bwt ~ sex,
  random = ~ animal + byear + mother,
  ginv = list(animal = Ainv), data = gryphon,
  nitt = 65000, thin = 50, burnin = 15000,
  prior = prior1.4, verbose = FALSE
)

posterior.mode(model1.4$VCV)</pre>
```

```
animal byear mother units 2.206574 0.813384 1.174485 1.698967
```

Here partitioning of significant maternal variance has resulted in a further decrease in V_R but also a decrease in V_A . The latter is because maternal effects of the sort we simulated (fixed differences between mothers) will have the consequence of increasing similarity among maternal siblings. Consequently they can look very much like an additive genetic effects and if present, but unmodelled, represent a type of 'common environment effect' that can and will-cause upward bias in V_A and so h^2 . Let's compare the estimates of heritability from each of models 1.2, 1.3 and 1.4:

```
posterior.heritability1.3 <- model1.3$VCV[, "animal"] /
    (model1.3$VCV[, "animal"] + model1.3$VCV[, "byear"] + model1.3$VCV[, "units"])
posterior.heritability1.4 <- model1.4$VCV[, "animal"] /
    (model1.4$VCV[, "animal"] + model1.4$VCV[, "byear"] + model1.4$VCV[, "mother"] + model1.4$VCV[,
posterior.mode(posterior.heritability1.2)

    var1
0.5140724

posterior.mode(posterior.heritability1.3)</pre>
```

var1

0.4488873

```
posterior.mode(posterior.heritability1.4)
```

var1

0.3591046

3.0.7. Testing significance of variance components

While testing the significance of fixed effects by evaluating whether or not their posterior distributions overlap zero was simple and valid, this approach does not work for variance components. Variance components are bounded to be positive (given a proper prior), and thus even when a random effect is not meaningful, its posterior distribution will never overlap zero. Model comparisons can be performed using the deviance information criterion (DIC), although it should be noted that the properties of DIC are not well understood and that the DIC may be focused at the wrong level for most people's intended level of inference - particularly with non-Gaussian responses. The implementation of DIC in MCMCglmm is further described in the reference manual. DIC values are calculated by MCMCglmm by default. Briefly, DIC like other information criteria balance model fit and model complexity simultaneously, and small values of DIC are preferred. We can compare models 1.4 and 1.3, i.e., models with and without the mother term:

model1.3\$DIC

[1] 3550.419

model1.4\$DIC

[1] 3326.221

model 1.4 has a much lower DIC value. Since the maternal effect term is the only difference between the models, we can consider the inclusion of this term statistically justifiable. We should note however that DIC has a large sampling variance and should probably only be calculated based on much longer MCMC runs.

3.0.8. Further partitioning variance

A population can be further fragmented into different groups or categories (such as females and males, juveniles and adults or treated and untreated). Some scientific questions require further and deeper analysis of the variance. To

avoid multiple model (one for each group), we can directly partition the variance between groups in a unique model. In addition, by doing so, we can also test if the variance are different between groups.

As example, we can partition the additive genetic variance and residual variance by sex. It is impossible to further partition the other variances but complexity an animal model requires sufficient sample size.

```
prior1.4.SEX <- list(
   G = list(G1 = list(V = diag(2), nu = 1.002), G2 = list(V = 1, nu = 0.002), G3 = list(V = 1, nu
   R = list(V = diag(2), nu = 1.002)
)

model1.4.SEX <- MCMCglmm(bwt ~ sex,
   random = ~ idh(sex):animal + byear + mother,
   rcov = ~ idh(sex):units,
   ginv = list(animal = Ainv), data = gryphon, nitt = 65000, thin = 50, burnin = 15000,
   prior = prior1.4.SEX, verbose = FALSE
)

posterior.mode(model1.4.SEX$VCV)</pre>
```

```
sex1.animal sex2.animal byear mother sex1.units sex2.units 1.2062736 2.0902893 0.8733524 1.2895559 2.2515435 1.8513554
```

```
posterior.heritability1.4.FEM <- model1.4.SEX$VCV[, "sex1.animal"] /
    (model1.4.SEX$VCV[, "sex1.animal"] + model1.4.SEX$VCV[, "byear"] +
        model1.4.SEX$VCV[, "mother"] + model1.4.SEX$VCV[, "sex1.units"])

posterior.heritability1.4.MAL <- model1.4.SEX$VCV[, "sex2.animal"] /
    (model1.4.SEX$VCV[, "sex2.animal"] + model1.4.SEX$VCV[, "byear"] +
        model1.4.SEX$VCV[, "mother"] + model1.4.SEX$VCV[, "sex2.units"])</pre>
```

var1

0.220252

```

```

var1 0.3716178

HPDinterval(posterior.heritability1.4.MAL, 0.95)

```
lower upper var1 0.04439791 0.5943772 attr(,"Probability")
[1] 0.95
```

Here, we can estimate the heritability for each sex. Both doesn't overlap with zero, so we can conclude both sexes have significant heritability. However due to their overlaps CIs, we can not conclude the heritability is not significantly different between sexes. An important quote to remember is "A difference in significance is not a significant difference"

```
h2.sex <- rbind(
    cbind(posterior.mode(posterior.heritability1.4.FEM), HPDinterval(posterior.heritability1.4.FEM, cbind(posterior.mode(posterior.heritability1.4.MAL), HPDinterval(posterior.heritability1.4.MAL,))

plot(c(0.95, 1.05) ~ h2.sex[, 1], xlim = c(0, 0.8), ylim = c(0.5, 1.5), , xlab = "", ylab = "", carrows(y0 = 0.95, x0 = h2.sex[1, 2], y1 = 0.95, x1 = h2.sex[1, 3], code = 3, angle = 90, length = arrows(y0 = 1.05, x0 = h2.sex[2, 2], y1 = 1.05, x1 = h2.sex[2, 3], code = 3, angle = 90, length = mtext("Narrow-sense heritability (±CI)", side = 1, las = 1, adj = 0.4, line = 3, cex = 1.6)

axis(2, at = 1, labels = c("birth weight"), las = 3, cex.axis = 1.6)
```

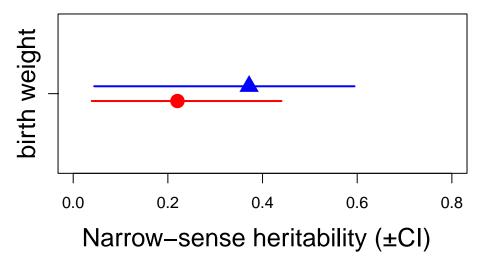

Figure 3.4.: Female and male heritability of birth weight

3.0.9. Modification of model parameter

Unfortunately (to our knowledge), it is not possible to alter the variance matrices and refit them within the model.

3.0.10. Covariance between two random effects

Some research questions require to estimate the covariance between two random effects within a univariate model. To do so, we can use the argument str. A similar argument or linking function mm can be used but it will forced the variance of animal and mother to be equal and the covariance to 1. As an example, we fit a model which estimate the covariance between the additive genetic variance and the mother variance. Both variances require to operate on the same level, thus animal and mother require to be associated to the pedigree information. The ginverse list name has to correspond to the first term in the argument or linking function

```
prior1.5 <- list(
   G = list(G1 = list(V = diag(2), nu = 0.002)),
   R = list(V = 1, nu = 0.002)
)

model1.5 <- MCMCglmm(bwt ~ sex,
   random = ~ str(animal + mother), ginv = list(animal = Ainv),
   rcov = ~ idh(1):units,</pre>
```

```
data = gryphon, nitt = 65000, thin = 50, burnin = 15000,
  prior = prior1.5, verbose = FALSE
)

posterior.mode(model1.5$VCV)
```

Chapter 4

brms

4.0.1. Running the model

First we need to load the brms library:

```
library(brms)
```

```
Loading required package: Rcpp

Loading 'brms' package (version 2.21.0). Useful instructions

can be found by typing help('brms'). A more detailed introduction

to the package is available through vignette('brms_overview').

Attaching package: 'brms'

The following object is masked from 'package:stats':

ar
```

To be able to fit an animal model, brms needs the relativeness (relationship) matrix of the pedigree and not its inverse (as in other softwares). This can be estimated using the nadiv package created by Pr. Matthew Wolak (https://cran.r-project.org/web/packages/nadiv/index.html).

```
Amat <- as.matrix(nadiv::makeA(gryphonped))</pre>
```

We are now ready to specify our first model: The structure of a bmrs model is similar to lme4, thus the random effect is added to the model with the term (1 | gr(animal, cov = Amat) which associate the id animal to the matrix of relativeness. In addition to the synthase of lme4, we includes other features or parameters within the models such as chain which represent the number of Markov chains (defaults to 4), core which represents the number of cores to use when executing the chains in parallel and iter which represents the number of total iterations per chain. For more parameters such as thin or warmup/burnin, you can read the Cran R page of the package (https://cran.r-project.org/web/packages/brms/brms.pdf)

bmrs is a Bayesian Multilevel Models using Stan, doing so we can apply a prior to the model to better shape the distribution of the different variances estimated by the model. Given that bmrs fit the model using a Bayesian approach via the software stan, we need to specify priors for the model. Default priors in brms work relatively well, however we strongly suggest to carefully select an adequate prior for your analysis. In this tutorial we will use the default priors. To get the prior used by default, we can use the get_prior() function.

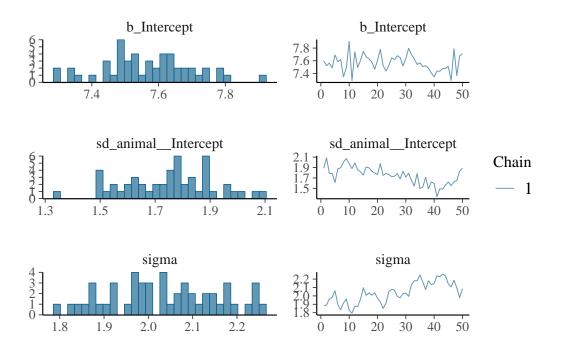

```
brms_m1.1 <- brm(
  bwt ~ 1 + (1 | gr(animal, cov = Amat)),
  data = gryphon,
  data2 = list(Amat = Amat),
  family = gaussian(),
  chains = 1, cores = 1, iter = 100
)

save(brms_m1.1, file = "data/brms_m1_1.rda")</pre>
```

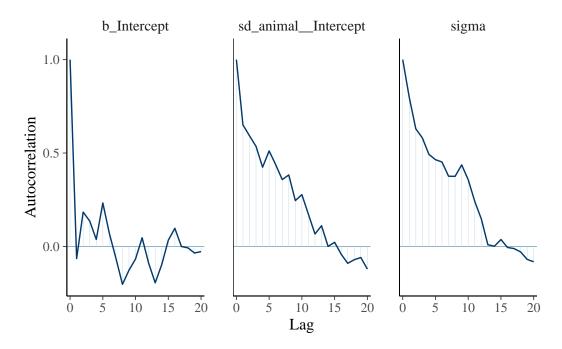

The result of the long model calculation is save in a spare file brms_m1_1.rda". To help readers, we can directly reloading it. Two distinct plot can be produce to produce some diagnostics graphs mcmc_plot.Note, that sigma represents the residual standard deviation.

Next, we examine (or directly using the model) the variance estimate and their distributions (via summary or plot).

```
load("data/brms_m1_1.rda")
plot(brms_m1.1)
```

summary(brms_m1.1)

Warning: Parts of the model have not converged (some Rhats are > 1.05). Be careful when analysing the results! We recommend running more iterations and/or setting stronger priors.

Family: gaussian

```
Links: mu = identity; sigma = identity
Formula: bwt ~ 1 + (1 | gr(animal, cov = Amat))
   Data: gryphon (Number of observations: 854)
Draws: 1 chains, each with iter = 100; warmup = 50; thin = 1;
   total post-warmup draws = 50
```

Multilevel Hyperparameters:

```
~animal (Number of levels: 1084)
```

Estimate Est.Error 1-95% CI u-95% CI Rhat Bulk_ESS Tail_ESS sd(Intercept) 1.75 0.17 1.49 2.06 1.55 2 20

Regression Coefficients:

Estimate Est.Error 1-95% CI u-95% CI Rhat Bulk_ESS Tail_ESS Intercept 7.57 0.13 7.30 7.79 1.00 27 63

Further Distributional Parameters:

Estimate Est.Error 1-95% CI u-95% CI Rhat Bulk_ESS Tail_ESS sigma 2.04 0.12 1.83 2.25 1.68 2 20

Draws were sampled using sampling(NUTS). For each parameter, Bulk_ESS and Tail_ESS are effective sample size measures, and Rhat is the potential scale reduction factor on split chains (at convergence, Rhat = 1).

The plot of variance showed that the different variances have an normal distribution, the autocorrelation plot or 'acf' show that the autocorrelation is close to 0. The summary exposes the mean (Estimate) of each variance or fixed effect (here just the intercept) associated to their posterior distribution with standard deviation (Est.Error) and two-sided 95% Credible intervals. Rhat provides information on the estimate convergence. If it's greater than 1, the chains have not yet converged and it will be require to run more iterations and/or set stronger priors. ESS represents the Effective sample values as the number of independent samples from the posterior distribution. However, for the purpose of this guide, the Rhat values are acceptable.

It is also possible to calculate the heritability using the function 'as.mcmc'

```
v_animal <- (VarCorr(brms_m1.1, summary = FALSE)$animal$sd)^2
v_r <- (VarCorr(brms_m1.1, summary = FALSE)$residual$sd)^2
h.bwt.1 <- as.mcmc(v_animal / (v_animal + v_r))
summary(h.bwt.1)</pre>
```

4.0.2. Adding fixed effects

To add effects to a univariate model, we simply modify the priors and the fixed effect portion of the model specification:

```
brms_m1.2 <- brm(
  bwt ~ 1 + sex + (1 | gr(animal, cov = Amat)),
  data = gryphon,
  data2 = list(Amat = Amat),
  family = gaussian(),
  chains = 2, cores = 2, iter = 1000
)
save(brms_m1.2, file = "data/brms_m1_2.rda")</pre>
```

To save time, the results of the calculation is stored in the spare file brms_m1_2.rda". We can assess the significance of sex as a fixed effect by examining its posterior distribution.

```
load("data/brms_m1_2.rda")
summary(brms_m1.2)
Family: gaussian
  Links: mu = identity; sigma = identity
Formula: bwt ~ 1 + sex + (1 | gr(animal, cov = Amat))
   Data: gryphon (Number of observations: 854)
  Draws: 2 chains, each with iter = 1000; warmup = 500; thin = 1;
         total post-warmup draws = 1000
Multilevel Hyperparameters:
~animal (Number of levels: 1084)
              Estimate Est.Error 1-95% CI u-95% CI Rhat Bulk_ESS Tail_ESS
sd(Intercept)
                  1.67
                            0.14

The posterior distribution of the sex2 term does not overlap zero. Thus, we can infer that sex has an effect on birth weight (presence of a sexual dimorphism) in this model and is a useful addition to the model, for most purposes. It is also worth noting that the variance components have changed slightly:

In fact since sex effects were previously contributing to the residual variance of the model our estimate of V_R (denoted 'units' in the output) is now slightly lower than before. This has an important consequence for estimating heritability since if we calculate V_P as $V_A + V_R$ then as we include fixed effects we will soak up more residual variance driving V_P . Assuming that V_A is more or less unaffected by the fixed effects fitted then as V_P goes down we expect our estimate of h^2 will go up.

```

```

Here h^2 has increased slightly from 0.5010 to 0.4192 (again, your values may differ slightly due to Monte Carlo error). Which is the better estimate? It depends on what your question is. The first is an estimate of the proportion of variance in birth weight explained by additive effects, the latter is an estimate of the proportion of variance in birth weight after conditioning on sex that is explained by additive effects. An important piece of advice, each researcher should be consistent in how they name their estimates and always correctly describe which estimates they are using conditional or not (to avoid any confusion).

4.0.3. Adding random effects

This is done by simply modifying the model statement in the same way, but requires addition of a prior for the new random effect. For instance, we can fit an effect of birth year:

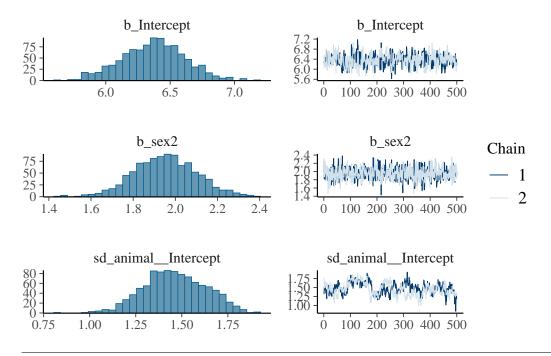

```
brms_m1.3 <- brm(
    bwt ~ 1 + sex + (1 | gr(animal, cov = Amat)) + (1 | byear) + (1 | mother),
    data = gryphon,
    data2 = list(Amat = Amat),
    family = gaussian(),
    chains = 2, cores = 2, iter = 1000
)</pre>
```

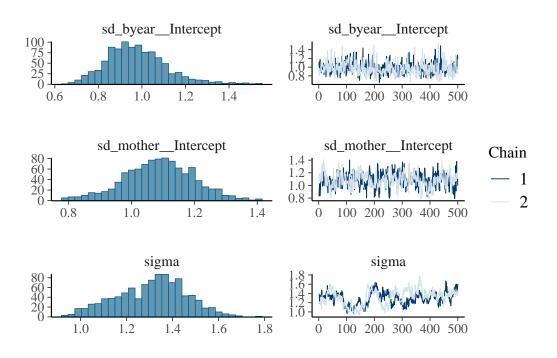

```
save(brms_m1.3, file = "data/brms_m1_3.rda")
```

To save time, the results of the calculation is stored in the spare file brms_m1_3.rda". We can assess the significance of sex as a fixed effect by examining its posterior distribution.

```
load("data/brms_m1_3.rda")
plot(brms_m1.3, ask = FALSE, N = 3)
```

Warning: Argument 'N' is deprecated. Please use argument 'nvariables' instead.

summary(brms_m1.3)\$random

Warning: Parts of the model have not converged (some Rhats are > 1.05). Be careful when analysing the results! We recommend running more iterations and/or setting stronger priors.

Here partitioning of significant birth year and maternal variance has resulted in a further decrease in V_R but also a decrease in V_A . The latter is because maternal effects of the sort we simulated (fixed differences between mothers) will have the consequence of increasing similarity among maternal siblings. Consequently they can look very much

like an additive genetic effects and if present, but unmodelled, represent a type of 'common environment effect' that can - and will- cause upward bias in V_A and so h^2 . Let's compare the estimates of heritability from each of models 1.2, 1.3 and 1.4:

```

N = 1000 Bandwidth = 0.01967

4.0.4. Testing significance of variance components

While testing the significance of fixed effects by evaluating whether or not their posterior distributions overlap zero was simple and valid, this approach does not work for variance components. Variance components are bounded to be positive (given a proper prior), and thus even when a random effect is not meaningful, its posterior distribution will never overlap zero.

Model comparisons can be performed using the function loo_compare using waic or weighted AIC.

```
brms_m1.3 <- add_criterion(brms_m1.3, "loo")</pre>
```

Warning: Found 364 observations with a pareto_k > 0.67 in model 'brms_m1.3'. We recommend to run more iterations to get at least about 2200 posterior draws to improve LOO-CV approximation accuracy.

```
brms_m1.1 <- add_criterion(brms_m1.1, "loo")</pre>
```

Warning: Found 476 observations with a pareto_k > 0.41 in model 'brms_m1.1'. We recommend to run more iterations to get at least about 2200 posterior draws to improve LOO-CV approximation accuracy.

```
loo_compare(brms_m1.3, brms_m1.1, criterion = "loo")
```

4.0.5. Further partitioning of the variance

Depending of the research question and the presence of different group within the dataset, brms allowed to partition the variance at different groups. Two distinct approach can be done to partition the different random effect: using an extra argument by=sex or by adding (0+sex|) before the |. Notes, here we used || which not estimate a possible covariance between groups (female and male) for the random effect.

```
brms_m1.4 <- brm(
    # bwt ~ 1 + sex + (1 | gr(animal, cov = Amat, by = sex))+ (1 | gr(byear, by = sex)) + (1 | gr
    bwt ~ 1 + sex + (0 + sex || gr(animal, cov = Amat)) + (0 + sex || byear) + (0 + sex || mother),
    data = gryphon,

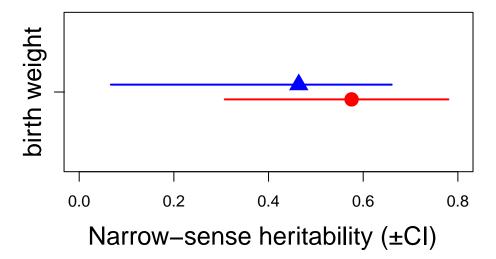

Figure 4.1.: Female and male heritability of birth weight

4.0.6. Modification of model parameter

Unfortunately (to our knowledge), it is not possible to alter the variance matrices and refit them within the model.

4.0.7. Covariance between two random effects

Some research questions require to estimate the covariance between two random effects within a univariate model. Unfortunately (to our knowledge), it is not possible to create a covariance between distinct random effects (https://github.com/paul-buerkner/brms/issues/502). However,a multi-membership model can be fit using the linking.function mm, thus forcing the variance of two variables to be equal and the covariance to 1.

Part II.

Multivariate animal model

This tutorial will demonstrate how to run a multivariate animal model looking at birth weight and tarsus length of the phenomenal gryphons.

Scenario and data

Scenario

Since natural selection rarely acts on single traits, to understand how birth weight might evolve in our population of gryphons, we may also want to think about possible covariance with other traits. If tarsus length at fledging is also under positive selection, what implications does it have for birth weight and vice versa? If the two traits are positively genetically correlated then this will facilitate evolution of larger size (since response of one trait will induce a positively correlated response in the other). If there is negative genetic covariance then this could act as an evolutionary constraint.

Using multivariate models allows the estimation of parameters relating to each trait alone (i.e. V_A , h^2 , etc), but also yields estimates of covariance components between traits. These include the (additive) genetic covariance COV_A which is often rescaled to give the additive genetic correlation r_A . However, covariance can also arise through other random effects (e.g. maternal covariance) and these sources can also be explicitly modeled in a bivariate analysis.

gryphon files

gryphonpedigree and phenotypic data files are the same as those used in tutorial 1 (*i.e.*, gryphonped.csv and gryphon.csv respectively).

Reading the data

```
gryphon <- read.csv("data/gryphon.csv")
gryphon$animal <- as.factor(gryphon$animal)
gryphon$mother <- as.factor(gryphon$mother)
gryphon$byear <- as.factor(gryphon$byear)
gryphon$sex <- as.factor(gryphon$sex)
gryphon$bwt <- as.numeric(gryphon$bwt)
gryphon$tarsus <- as.numeric(gryphon$tarsus)</pre>
```

Reading the pedigree

```
gryphonped <- read.csv("data/gryphonped.csv")
gryphonped$id <- as.factor(gryphonped$id)
gryphonped$father <- as.factor(gryphonped$father)
gryphonped$mother <- as.factor(gryphonped$mother)</pre>
```

Chapter 5

Asreml-R

5.0.1. Running the model

First we need to load the asreml library:

```
library(asreml)
```

Loading required package: Matrix

Attaching package: 'Matrix'

The following objects are masked from 'package:tidyr':

expand, pack, unpack

Online License checked out Fri Apr 5 15:37:37 2024

Loading ASReml-R version 4.2

For running multivariate analyses in ASReml-R, the code is slightly more complex than for the univariate case. This is because ASReml-R allows us to make different assumptions about the way in which traits might be related. We need to explicitly specify a covariance structure with difference covariance functions us(), idh() or corgh() which for example would estimate an unconstrained (co)variance matrix, an identity matrix and a variance and correlation matrix repestively. We can also specify some starting values for the variance matrices. These can be

very approximate *guestimates* or not at all, but having reasonable starting values can help convergence. It is also possible to let the model running without specifying starting values. Finally, we have increased the default maximum number of iterations (maxiter) which can help to achieve convergence for more complicated models. Another way to increase the number of iteration will be to use the update function. Notes that if the LogLik is not stabilized after several iterations, it is good indication of the model require more iteration.

```
ainv <- ainverse(gryphonped)

modela <- asreml(
   fixed = cbind(bwt, tarsus) ~ trait,
   random = ~ us(trait, init = c(1, 0.1, 1)):vm(animal, ainv),
   residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
   data = gryphon,
   na.action = na.method(x = "include", y = "include"),
   maxit = 20
)</pre>
```

modela has fitted a bivariate model of bwt and tarsus, with the mean for each of the traits as a fixed effect (trait). The additive genetic variance-covariance matrix (\mathbf{G}) is unstructured (us; *i.e.* all elements are free to vary) and the starting values for V_A for bwt, COV_A between bwt and tarsus, and V_A for tarsus are set to 1, 0.1 and 1, respectively. Similarly, the residual matrix is unstructured and uses the same starting values.

Note that the argument na.action = na.method(x = "include", y = "include") can be added to the model. In a bivariate model, it will help calculate the covariance between two traits with different missing information NA and so help imbalance phenotypage and save sample size. However, it is important to scale (mean =0, var = 1) the two traits to correctly adjust the model(see Asreml-R manual for more information).

Let's have a look at the variance components, and notice that there are now seven (co)variance components reported in the table:

summary(modela)\$varcomp

	component	std.error	z.ratio	bound

<pre>trait:vm(animal, ainv)!trait_tarsus:bwt</pre>	0			
<pre>trait:vm(animal, ainv)!trait_tarsus:tarsus</pre>	0			
units:trait!R	0			
units:trait!trait_bwt:bwt	0			
units:trait!trait_tarsus:bwt	0			
units:trait!trait_tarsus:tarsus	0			

The first three terms are related to the genetic matrix and, in order are $V_{A,bwt}$, COV_A , $V_{A,tarsus}$. Below is again a line where the units:traitr!R component equals to 1, which again can be ignored. The final three terms relate to the residual matrix and correspond to $V_{R,bwt}$, COV_R , $V_{R,tarsus}$. Based on our quick and dirty check (is z.ratio > 1.96?) all components look to be statistically significant.

We can calculate the genetic correlation as $COV_A/\sqrt{V_{A,bwt}\cdot V_{A,tarsus}}$. Thus this model gives an estimate of r_A = 0.38. It is also possible to estimate the residual correlation r_{res} = 0.4.

Both correlations are distinct in nature. The genetic correlation reflects how much the traits are linked by genetic via polygenic effect or linkage desequilibrium, whereas the residual correlation reflects the environmental correlation or errors measurement correlation.

Although we can calculate this by hand, we can also use vpredict(), which also provides an (approximate) standard error:

```
vpredict(modela, r_A ~ V2 / sqrt(V1 * V3))
```

Estimate SE r_A 0.3814436 0.1299759

```
vpredict(modela, r_res ~ V6 / sqrt(V5 * V7))
```

Estimate SE r_res 0.4019799 0.08607104

Of course we can also calculate the heritability of bwt and tarsus from this model:

```
vpredict(modela, h2.bwt ~ V1 / (V1 + V5))
```

Estimate SE

h2.bwt 0.466646 0.07671533

vpredict(modela, h2.tarsus ~ V3 / (V3 + V7))

Estimate SE

h2.tarsus 0.4116331 0.09305863

5.0.2. Adding fixed and random effects

Fixed and random effects can be added just as for the univariate case. Given that our full model of bwt from tutorial 1 had sex as a fixed effect as well as birth year and mother as random effects, we could specify a bivariate formulation with the same complexity:

```
modelb <- asreml(
  fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
  random = ~ us(trait, init = c(1, 0.1, 1)):vm(animal, ainv) +
    us(trait, init = c(1, 0.1, 1)):byear +
    us(trait, init = c(1, 0.1, 1)):mother,
  residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
  data = gryphon,
  na.action = na.method(x = "include", y = "include"),
  maxit = 20
)</pre>
```

ASReml Version 4.2 05/04/2024 15:37:37

units:trait!trait_bwt:bwt	P 0		
units:trait!trait_tarsus:bwt	P 0		
units:trait!trait_tarsus:tarsus	P 0		

we can estimate the different correlations using vpredict:

```
vpredict(modelb, r_byear ~ V2 / sqrt(V1 * V3))
```

Estimate SE

r_byear 0.08508312 0.2134209

```
vpredict(modelb, r_M ~ V5 / sqrt(V4 * V6))
```

Estimate SE

r_M -0.6627518 0.2487963

```
vpredict(modelb, r_A ~ V8 / sqrt(V7 * V9))
```

Estimate SE

r_A 0.7353053 0.1094747

```
vpredict(modelb, r_res ~ V12 / sqrt(V11 * V13))
```

Estimate SE

r_res 0.8365729 0.07366762

Now we can look at the fixed effects parameters and assess their significance with a conditional Wald F-test:

solution std error z.ratio

trait_bwt 6.3844483 0.2328210 27.4221324

5.0.3. Significance testing

Under the model above r_M is estimated as -0.66 and the z.ratio associated with the corresponding covariance (COV_M) is >2 (in absolute terms). We might therefore infer that there is evidence for a strong negative correlation between the traits with respect to the mother and that while maternal identity explains variance in both traits those mothers that tend to produce heavier offspring actually tend to produce offspring with shorter tarsus lengths.

To formally test if COV_M is significantly different from zero, we can compare the log-likelihood for this model:

modelb\$loglik

[1] -2380.246

to a model in which we specify that COV_M =0. Since this constraint reduces the number of parameters to be estimated by one, we can use a likelihood ratio test (LRT) with one degree of freedom. To run the constrained model, we modify the G structure defined for the mother random effect to diagonal (diag), which means we only estimate the variances (the diagonal of the matrix) but not the covariance (the covariance are fixed to 0):

```
modelc <- asreml(
    fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
    random = ~ us(trait, init = c(1, 0.1, 1)):vm(animal, ainv) +
        us(trait, init = c(1, 0.1, 1)):byear +
        diag(trait, init = c(1, 1)):mother,
    residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
    data = gryphon,
    na.action = na.method(x = "include", y = "include"),
    maxit = 20
)</pre>
```

ASReml Version 4.2 05/04/2024 15:37:39

	LogLik	Sigma2	DF	wall	
1	-4677.820	1.0	1533	15:37:39	
2	-4010.442	1.0	1533	15:37:39	
3	-3275.409	1.0	1533	15:37:40	
4	-2763.519	1.0	1533	15:37:40	
5	-2483.732	1.0	1533	15:37:40	
6	-2400.242	1.0	1533	15:37:40	
7	-2386.663	1.0	1533	15:37:40	
8	-2386.049	1.0	1533	15:37:40	
9	-2386.045	1.0	1533	15:37:40	

You can run summary (modelc) \$varcomp to confirm this worked. We can now obtain the log-likelihood of this model and compare this to that of modelb using a likelihood ratio test:

modelc\$loglik

```
[1] -2386.045
```

We can see that the model log-likelihood is now -2386.05. And comparing the models using a likelihood ratio test:

```
2 * (modelb$loglik - modelc$loglik)
```

[1] 11.59835

So our chi-square test statistic is χ_1^2 = 11.6. The p-value that goes with this is obtained by:

```
1 - pchisq(2 * (modelb$loglik - modelc$loglik), 1)
```

[1] 0.0006601037

We would therefore conclude that the maternal covariance is significantly different from zero.

We could apply the same procedure to show that the residual (environmental) covariance and the genetic covariance estimates are significantly greater than zero (*i.e.*, heavier individuals tend to have longer tarsus lengths). In contrast, we should find that the byear covariance between the two traits is non-significant.

```
modeld <- asreml(
  fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
  random = ~ us(trait, init = c(1, 0.1, 1)):vm(animal, ainv) +
    diag(trait, init = c(1, 1)):byear +
    us(trait, init = c(1, 0.1, 1)):mother,
  residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
  data = gryphon,
  na.action = na.method(x = "include", y = "include"),
  maxit = 20
)</pre>
```

5.0.4. Estimate directly the genetic correlation within the model

Within Asreml-r, different matrix structure can be specify such as us,corg, diag, etc (cf see the Asreml-r guide). Instead of the fitting an unstructured matrix with the argument us or a reduced model with no covariance with the argument diag, we can also directly estimate the genetic correlation between the bwt and tarsus with corgh.

Here we decide to estimate directly the additive genetic correlation.

```
modele <- asreml(
  fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
  random = ~ corgh(trait, init = c(0.1, 1, 1)):vm(animal, ainv) +
    us(trait, init = c(1, 0.1, 1)):byear +
    us(trait, init = c(1, 0.1, 1)):mother,
  residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
  data = gryphon,
  na.action = na.method(x = "include", y = "include"),
  maxit = 20
)</pre>
```

```

```

It is important to note that using corgh change the order of the estimate (co)variance/correlation. Thus, the initial values need to be reorder and all different calculation need to be adjust in consequence. It is also important to check the difference between the model with us and corgh to make sure any mistake are made.

```
summary(modelb)$loglik
```

[1] -2380.246

```
summary(modele)$loglik
```

[1] -2380.246

There two main advantages to use corgh: first, a direct estimation of correlation within the G matrix can avoid mistake in the vpredict calculation; second, it is possible to test if the correlation is significantly different than 0 (similar result as LRT with the covariance) but also to -1 and 1 which correspond of the correlation boundaries. The following code showed how to create a reduced model with the correlation close to 1 and compared to the initial model. Since we compared the correlation to its boundary, the degree of freedom is only half as a one tail LTR.

```
MODEL_MODIF <- update.asreml(modele, start.values = T)

G_MOD <- MODEL_MODIF$vparameters.table[(1:9), ]

G_MOD[1, 2] <- 0.99999

G_MOD[1, 3] <- "F"</pre>
```

```
modele.red <- asreml(
    fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
    random = ~ corgh(trait, init = c(0.1, 1, 1)):vm(animal, ainv) +
        us(trait, init = c(1, 0.1, 1)):byear +
        us(trait, init = c(1, 0.1, 1)):mother,
    residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
    data = gryphon,
    na.action = na.method(x = "include", y = "include"),
    maxit = 20,
    G.param = G_MOD
)</pre>
```

2 * (modele\$loglik - modele.red\$loglik)

[1] 5.544679

```
1 - pchisq(2 * (modele$loglik - modele.red$loglik), df = 0.5)
```

[1] 0.006598676

Here, the correlation is significantly different than 1 (~0.99999).

5.0.5. Visualisation of the correlation (aka BLUP extraction)

When estimating correlation between traits, having a visualization of it can help the interpretation. In addition, visualizing the correlation can spot outliers in the dataset. Thanks to mixed model, each breeding values is stored within the model and can be extract as BLUP (Best Linear Unbiased Predictor).BLUP should be normally distributed, if not you need to check the assumption of your animal model.

To simplify the following code, we rename the variable T1 and T2.

```
gryphon$T1 <- gryphon$bwt
gryphon$T2 <- gryphon$tarsus

###########

modele <- asreml(
    fixed = cbind(T1, T2) ~ trait + at(trait):sex,
    random = ~ corgh(trait, init = c(0.1, 1, 1)):vm(animal, ainv) +
        us(trait, init = c(1, 0.1, 1)):byear +
        us(trait, init = c(1, 0.1, 1)):mother,
    residual = ~ id(units):us(trait, init = c(1, 0.1, 1)),
    data = gryphon,
    na.action = na.method(x = "include", y = "include"),
    maxit = 20
)</pre>
```

```

5.0.6. Partitionning (co)variance between groups

Similar to the univariate model, it is possible to partition the variance and also the covariance between different groups within the dataset. Here, we can estimate sex-specific genetic correlation. Note, to partition a correlation, it is require to have important sample size within each group. For this example, we simplify the model!

```
gryphon <- gryphon[order(gryphon$sex), ]
model_sex <- asreml(
    fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
    random = ~ at(sex):us(trait, init = c(1, 0.1, 1)):vm(animal, ainv) +
        us(trait, init = c(1, 0.1, 1)):byear +
        us(trait, init = c(1, 0.1, 1)):mother,
    residual = ~ dsum(~ id(units):us(trait) | sex),
    data = gryphon,
    na.action = na.method(x = "include", y = "include"),
    maxit = 20
)</pre>
```

we can estimate the different correlations using vpredict:

```
vpredict(model_sex, r_byear ~ V2 / sqrt(V1 * V3))
```

Estimate SE

r_byear 0.07681584 0.213141

```
vpredict(model_sex, r_M ~ V5 / sqrt(V4 * V6))
```

Estimate SE

 $r_M - 0.6429092 0.248944$

```
vpredict(model_sex, r_A.1 ~ V8 / sqrt(V7 * V9))
```

Estimate SE

r_A.1 0.8282059 0.1723596

```
vpredict(model_sex, r_A.2 ~ V11 / sqrt(V10 * V12))
       Estimate
                       SE
r_A.2 0.9642225 0.1241668
vpredict(model_sex, r_res.1 ~ V15 / sqrt(V14 * V16))
         Estimate
                          SE
r_res.1 0.7938355 0.07892634
vpredict(model_sex, r_res.2 ~ V19 / sqrt(V18 * V20))
         Estimate
                         SE
r_res.2 0.6341057 0.1894837
and the heritability too:
vpredict(model_sex, h2.bwt.1 ~ V7 / (V1 + V4 + V7 + V14))
          Estimate
                           SE
h2.bwt.1 0.2246768 0.09176827
vpredict(model_sex, h2.bwt.2 ~ V10 / (V1 + V4 + V10 + V18))
          Estimate
                          SE
h2.bwt.2 0.3119425 0.1442547
vpredict(model_sex, h2.tarsus.1 ~ V9 / (V3 + V6 + V9 + V16))
            Estimate
                            SE
h2.tarsus.1 0.21422 0.1070464
```

```
vpredict(model_sex, h2.tarsus.2 ~ V12 / (V3 + V6 + V12 + V20))
```

Estimate SE

h2.tarsus.2 0.4492383 0.1833858

Now we can look at the fixed effects parameters and assess their significance with a conditional Wald F-test:

```
solution std error z.ratio
trait_bwt 6.3779149 0.2311766 27.5889321
trait_tarsus 20.5838787 0.4942649 41.6454395
at(trait, 'bwt'):sex_1 0.0000000 NA NA
at(trait, 'bwt'):sex_2 1.9393688 0.1903239 10.1898321
at(trait, 'tarsus'):sex_1 0.0000000 NA NA
at(trait, 'tarsus'):sex_2 -0.0554799 0.4758708 -0.1165861
```

```

To assess the significant of the covariance, a LTR test can be done with a reduced model where a specific covariance can be fixed to 0 (for example the female covariance, following code).

```
model_modif <- update.asreml(model_sex, start.values = T)

G <- model_modif$vparameters[(1:12), ]

G$Constraint[(2)] <- "F"

G$Value[(2)] <- 0</pre>
```

```
reduc.model_sex <- asreml(
    fixed = cbind(bwt, tarsus) ~ trait + at(trait):sex,
    random = ~ at(sex):us(trait, init = c(1, 0.1, 1)):vm(animal, ainv) +
        us(trait, init = c(1, 0.1, 1)):byear +
        us(trait, init = c(1, 0.1, 1)):mother,
    residual = ~ dsum(~ id(units):us(trait) | sex),
    data = gryphon,
    na.action = na.method(x = "include", y = "include"),
    maxit = 20,
    G.param = G
)</pre>
```

ASReml Version 4.2 05/04/2024 15:37:45

5.0.7. Between groups (co)variances and the B-matrix

Animal models are amazing model. With different group within a population, it is also possible to estimate how much the different groups shared the same genetic via the cross-group genetic covariance. This covariance is essential to understand ontogenic or sexual conflict, which can constraint or enhanced response to evolution. As an example, we estimate the cross-sex genetic correlation r_{fm}

First, we need to dissociate the trait values for females and males into distinct variables. Then, we use a bivariate model (for one trait: tarsus) and a multivariate model (for various traits: tarsus and bwt). With a multivariate model, the cross-sex-cross trait covariance matrix also named B matrix.

The coding is a bit complex but pretty straightforward. It is important to modify the covariance matrix at the residual level to avoid the calculation of a cross-sex residual covariance (no individual switched sex during the experiment).

```

```

The cross-sex genetic correlation can estimate form the output of the model. For tarsus length at fledging, sexes shared a lot of genetic variance which is commun for a trait with low sexual dimorphism. If the selection is antagonistic between males and females, sexes can not evolve freely form the other sexes and a sexual conflict appears.

We can estimate directly the correlation and plot the cross-sex genetic correlation

Chapter 6

MCMCgImm

MCMCglmm has the advantage to keep automatically keep the lines with missing data and will try to fit the model use latent variables for missing data. We will remove the missing values from the data before fitting the model.

```
gryphon2 <- subset(gryphon, !is.na(bwt) & !is.na(tarsus))</pre>
First load MCMCglmm:
library(MCMCglmm)
Loading required package: Matrix
Attaching package: 'Matrix'
The following objects are masked from 'package:tidyr':
    expand, pack, unpack
Loading required package: coda
Loading required package: ape
Attaching package: 'ape'
```

```
The following object is masked from 'package:dplyr': where
```

```
Ainv <- inverseA(gryphonped)$Ainv
```

6.0.1. Fitting the model

Fitting a multivariate model in MCMCglmm involves several new consideration above those for fitting univariate models. First, we have to fit multivariate priors; second, we have to specify the ways in which effects on different traits may covary, including the nature of residual (co)variation; and third, we will have to be a little more specific when specifying to MCMCglmm what type of distributions from which we assume our data are drawn. Our most basic model can be specified as:

```
prior2.1 <- list(
   G = list(G1 = list(V = diag(2), nu = 1.002)),
   R = list(V = diag(2), nu = 1.002)
)

model2.1 <- MCMCglmm(cbind(bwt, tarsus) ~ trait - 1,
   random = ~ us(trait):animal,
   rcov = ~ us(trait):units,
   family = c("gaussian", "gaussian"),
   ginv = list(animal = Ainv),
   data = gryphon2, prior = prior2.1, verbose = FALSE
)
summary(model2.1)</pre>
```

```
Iterations = 3001:12991
Thinning interval = 10
Sample size = 1000

Figure 6.1.: The posterior distribution of the additive genetic effect for tarsus length in a MCMCglmm run with default values

autocorr.diag(model2.1\$VCV)[, "traittarsus:traittarsus.animal"][2]

Lag 10

0.8297019

We have constructed the prior similarly to the those in the univariate models in tutorial 1, only we are specifying a 2x2 covariance matrix rather than a single variance. In order to provide proper priors, we have set the degree of belief parameter to greater than 1 (1.002). Those priors are not necessarily weak or uninformative in all circumstances. We will consider them adequate nonetheless for this tutorial. Please the vignette of the MCMCglmm packages (Hadfield 2010) for more information on priors. In tutorial 1, we used full autocorrelation tables to evaluate the validity of the posterior distribution. Note that we have not done this here.

For a bivariate model this table can become very complex. Nonetheless, it is worth evaluating, rather it is simply to large to include here. It can be viewed in the console as before. Here we have displayed only the autocorrelation for estimates of additive genetic effects for tarsus length with a lag of one samples (10 iterations given this MCMCglmm run with default values). This lag of 0.8297019 is clearly unacceptable. The posterior distribution of the additive genetic effect on tarsus length is shown in Figure 4, note the autocorrelation evident in the left-hand plot.

We will opt to run the analysis for longer. This longer run could be run using the following code (including a line to save the output):

```
model2.1 <- MCMCglmm(cbind(bwt, tarsus) ~ trait - 1,
    random = ~ us(trait):animal,
    rcov = ~ us(trait):units,
    family = c("gaussian", "gaussian"),
    ginv = list(animal = Ainv),
    data = gryphon2,
    nitt = 130000, thin = 100, burnin = 30000,
    prior = prior2.1, verbose = FALSE
)
save(model2.1, file = "data/MCMCglmm_model2_1_LongRun.rda")</pre>
```

However, this run might take as long as an hour. For the purpose of this tutorial we have provided an output for such a run. It can be obtained and manipulated as follows, assuming that the file MCMCglmm_model2_1_LongRun.rda is available at the specified location:

```
load(file = "data/MCMCglmm_model2_1_LongRun.rda")
autocorr.diag(model2.1$VCV)[, "traittarsus:traittarsus.animal"][2]
```

Lag 100 0.3501744

This level of autocorrelation is more acceptable, at least for the purpose of demonstration in this tutorial. We can recover variance components, heritabilities, and genetic correlations from the posterior distribution of this model:

```
posterior.mode(model2.1$VCV)
```

```
traitbwt:traitbwt.animal
3.471888
2.949939
traitbwt:traittarsus.animal
2.949939

4.012766
traitbwt:traitbwt.units
4.3876887
traitbwt:traittarsus.units
4.3876887
19.604460
```

```
heritability.bwt2.1 <- model2.1$VCV[, "traitbwt:traitbwt.animal"] / (model2.1$VCV[, "traitbwt:traitbwt:traitbwt.animal"] / (model2.1$VCV[, "traitbwt:traitbwt:traitbwt.animal"] / (model2.1$VCV[, "traitbwt:traitbass.animal"] / (model2.1$VCV[, "traitbass.animal"] / (model2.1$VCV[, "traitbass.animal"]
```

6.0.2. Adding fixed and random effects

Fixed and random effects can be added just as for the univariate case. Given that our full model of bwt from tutorial 1 had sex as a fixed effect as well as random effects of byear and mother, we could specify a bivariate formulation of this using the following code (including a line to save the output):

```
prior2.2 <- list(
    G = list()
    G1 = list(V = diag(2), nu = 1.002),
    G2 = list(V = diag(2), nu = 1.002),
    G3 = list(V = diag(2), nu = 1.002)
),
    R = list(V = diag(2), nu = 1.002)
)
model2.2 <- MCMCglmm(cbind(bwt, tarsus) ~ trait - 1 + trait:sex,
    random = ~ us(trait):animal + us(trait):byear + us(trait):mother,</pre>
```

```
rcov = ~ us(trait):units,
family = c("gaussian", "gaussian"),
ginv = list(animal = Ainv), data = gryphon2,
nitt = 130000, thin = 100, burnin = 30000,
prior = prior2.2, verbose = FALSE
)
save(model2.2, file = "data/MCMCglmm_model2_2_LongRun.rda")
```

Again we have provided the data from one such run. It can be accessed using the code:

```
load(file = "data/MCMCglmm_model2_2_LongRun.rda")
summary(model2.2)
```

```
Iterations = 30001:129901
Thinning interval = 100
Sample size = 1000
```

                  4.3432849
                                                 15.0853981
```

```
genetic.correlation2.2 <- model2.2$VCV[, "traitbwt:traittarsus.animal"] / sqrt(model2.2$VCV[, "traitbwt:traittarsus.mother"] / sqrt(m
```

var1

0.6932486

```
posterior.mode(maternal.correlation2.2)
```

var1

-0.7431221

Evaluation of the statistical support for these genetic and maternal correlations is straightforward. Because we imposed no constraint on their estimation, we can evaluate the extent to which the posterior distributions overlap zero:

```
HPDinterval(genetic.correlation2.2, 0.95)
```

```
lower upper var1 0.3062932 0.9197543 attr(,"Probability")
[1] 0.95
```

HPDinterval(maternal.correlation2.2, 0.95)

```
lower upper var1 -0.9432297 -0.3210149 attr(,"Probability")
[1] 0.95
```

Neither or these posterior distributions overlaps zero, so we can consider them both statistically supported.

6.0.3. Partitioning (co)variances

As in the tutorial 1, it is possible to partition the variance-covariance matrix between groups (here sex) Note: the model is simplified without sex-specific covariance for the byear and mother random effect.

```
gryphon2 <- gryphon2[order(gryphon2$sex), ]</pre>
prior2.3 <- list(</pre>
  G = list(
    G1 = list(V = diag(2), nu = 1.002),
    G2 = list(V = diag(2), nu = 1.002),
    G3 = list(V = diag(2), nu = 1.002),
    G4 = list(V = diag(2), nu = 1.002)
  ),
  R = list(
    V1 = list(V = diag(2), nu = 1.002),
    V2 = list(V = diag(2), nu = 1.002)
  )
model2.4 <- MCMCglmm(cbind(bwt, tarsus) ~ trait - 1 + trait:sex,</pre>
  random = ~ us(at.level(sex, "1"):trait):animal + us(at.level(sex, "2"):trait):animal + idh(trai
  rcov = ~ us(at.level(sex, "1"):trait):units + us(at.level(sex, "2"):trait):units,
  family = c("gaussian", "gaussian"),
```

```
ginv = list(animal = Ainv), data = gryphon2,
nitt = 130000, thin = 100, burnin = 30000,
prior = prior2.3, verbose = FALSE, pr = TRUE,
)
save(model2.4, file = "data/MCMCglmm_model2_4_LongRun.rda")
```

Again we have provided the data from one such run. It can be accessed using the code:

```
load(file = "data/MCMCglmm_model2_4_LongRun.rda")
summary(model2.4)
```

```
Iterations = 30001:129901

```

Evaluation of the statistical support for these sex-specific correlations is straightforward. Because we imposed no constraint on their estimation, we can evaluate the extent to which the posterior distributions overlap zero or overlap each other:

```
HPDinterval(genetic.correlation2.4.F, 0.95)
```

```
lower
                    upper
var1 -0.3742433 0.963575

arrows(y0 = 2.05, x0 = cor.est[4, 2], y1 = 2.05, x1 = cor.est[4, 3], code = 3, angle = 90, length
mtext("Correlation (±CI)", side = 1, las = 1, adj = 0.4, line = 3, cex = 1.6)
axis(2, at = 1, labels = c("genetic"), las = 3, cex.axis = 1.6)
axis(2, at = 2, labels = c("residual"), las = 3, cex.axis = 1.6)
```

These posterior distributions overlap between each other, which suggested the correlation were not significantly different between sexes.

6.0.4. Between groups (co)variances and the B-matrix

Animal models are amazing model. With different group within a population, it is also possible to estimate how much the different groups shared the same genetic via the cross-group genetic covariance. This covariance is essential to understand ontogenic or sexual conflict, which can constraint or enhanced response to evolution. As an example, we estimate the cross-sex genetic correlation r_{fm}

First, we need to dissociate the trait values for females and males into distinct variables. Then, we use a bivariate model (for one trait: tarsus) and a multivariate model (for various traits: tarsus and bwt). With a multivariate model, the cross-sex-cross trait covariance matrix is also named B matrix.

The coding is a bit complain but pretty straightforward. It is important to modify the covariance matrix at the residual level to avoid the calculation of a cross-sex residual covariance (no individual switched sex during the experiment).

```
gryphon2$bwt.1 <- NA
gryphon2$tarsus.1 <- NA
animal <- gryphon2[gryphon2$sex == "1", ]$animal
for (i in unique(animal)) {
  gryphon2$bwt.1[which(gryphon2$animal == i)] <- gryphon2$bwt[which(gryphon2$animal == i)]</pre>
  gryphon2$tarsus.1[which(gryphon2$animal == i)] <- gryphon2$tarsus[which(gryphon2$animal == i)]</pre>
}
#
gryphon2$bwt.2 <- NA</pre>
gryphon2$tarsus.2 <- NA</pre>
animal <- gryphon2[gryphon2$sex == "2", ]$animal
for (i in unique(animal)) {
  gryphon2$bwt.2[which(gryphon2$animal == i)] <- gryphon2$bwt[which(gryphon2$animal == i)]</pre>
  gryphon2$tarsus.2[which(gryphon2$animal == i)] <- gryphon2$tarsus[which(gryphon2$animal == i)]</pre>
}
prior2.4 <- list(</pre>
  G = list(
    G1 = list(V = diag(2), nu = 1.002),

The cross-sex genetic correlation can estimate form the output of the model. For tarsus length at fledging, sexes shared a lot of genetic variance which is commun for a trait with low sexual dimorphism. If the selection is antagonistic between males and females, sexes can not evolve freely form the other sexes and a sexual conflict appears.

```
rfm <- model.BivSex$VCV[, "traittarsus.1:traittarsus.2.animal"] / sqrt(model.BivSex$VCV[, "traitt
posterior.mode(rfm)
     var1
0.9664439

```

#

The B matrix used the same code but in a multivariate animal model framework. Here some example code, however due to the nature of the dataset, the cross-sex genetic covariance for birth weight is hard to estimate making difficulty to fit this multivariate animal model.

```
prior2.5 <- list(
   G = list()
   G1 = list(V = diag(4), nu = 1.002),
   G2 = list(V = diag(4), nu = 1.002),
   G3 = list(V = diag(4), nu = 1.002)
),
   R = list(
   V1 = list(V = diag(4), nu = 1.002)
)

#
model.MultivSex <- MCMCglmm(cbind(tarsus.1, bwt.1, tarsus.2, bwt.2) ~ trait - 1,
   random = ~ us(trait):animal + idh(trait):byear + idh(trait):mother,
   rcov = ~ us(trait):units,
   family = c("gaussian", "gaussian", "gaussian", "gaussian"),
   ginv = list(animal = Ainv), data = gryphon2,
   nitt = 130000, thin = 100, burnin = 30000,
   prior = prior2.5, verbose = FALSE, pr = TRUE</pre>
```

```
save(model.MultivSex, file = "data/MCMCglmm_model_MultivSex_LongRun.rda")
```

Again we have provided the data from one such run. It can be accessed using the code:

```
load(file = "data/MCMCglmm_model_MultivSex_LongRun.rda")
summary(model.MultivSex)
```

Chapter 7

brms

```
First load brms:

library(brms)

Loading required package: Rcpp

Loading 'brms' package (version 2.21.0). Useful instructions
can be found by typing help('brms'). A more detailed introduction
to the package is available through vignette('brms_overview').

Attaching package: 'brms'

The following object is masked from 'package:stats':

ar

Amat <- as.matrix(nadiv::makeA(gryphonped))
```

7.0.1. Fitting the model

Fitting a multivariate model in brms involves several new consideration above those for fitting univariate models. First, we need to create two models/objects with the function bf fitting the desired univariate model structure for each

response variable (here bwt and tarsus). It is the equivalent of writing mvbf (bwt, tarsus), but the advantage to create two distinct model is to specific different model structure (fixed or random effect) for each response variable.

Then, the two objects/models are added into a third model to quantify all the estimates in addition to their covariance. Contrary to MCMCglmm or asreml-R, brms directly estimate the covariance and the correlation in its outputs. Our most basic model can be specified as:

```
bf_bwt <- bf(bwt ~ 1 + (1 | a | gr(animal, cov = Amat)))
bf_tarsus <- bf(tarsus ~ 1 + (1 | a | gr(animal, cov = Amat)))
brms_m2.1 <- brm(
    bf_bwt + bf_tarsus + set_rescor(TRUE),
    data = gryphon,
    data2 = list(Amat = Amat),
    chains = 2, cores = 2, iter = 1000
)
save(brms_m2.1, file = "data/brms_m2_1.rda")</pre>
```

Again we have provided the data from one such run. It can be accessed using the code:

```
load("data/brms_m2_1.rda")
summary(brms_m2.1)
```

Warning: Parts of the model have not converged (some Rhats are > 1.05). Be careful when analysing the results! We recommend running more iterations and/or setting stronger priors.

```
Family: MV(gaussian, gaussian)
Links: mu = identity; sigma = identity
mu = identity; sigma = identity

Formula: bwt ~ 1 + (1 | p | gr(animal, cov = Amat))
        tarsus ~ 1 + (1 | p | gr(animal, cov = Amat))

Data: gryphon (Number of observations: 683)

Draws: 2 chains, each with iter = 1000; warmup = 500; thin = 1;
        total post-warmup draws = 1000
```

Multilevel Hyperparameters:

~animal (Number of levels: 683)

	Estimate	Est.Error	1-95% CI	u-95% CI	Rhat
sd(bwt_Intercept)	1.81	0.21	1.41	2.20	1.06
<pre>sd(tarsus_Intercept)</pre>	3.44	0.43	2.49	4.25	1.05
<pre>cor(bwt_Intercept,tarsus_Intercept)</pre>	0.38	0.14	0.08	0.62	1.02
	Bulk_ESS	Tail_ESS			
sd(bwt_Intercept)	31	192			
<pre>sd(tarsus_Intercept)</pre>	61	173			
<pre>cor(bwt_Intercept,tarsus_Intercept)</pre>	101	232			

Regression Coefficients:

	Estimate	Est.Error	1-95% CI	u-95% (CI Rhat	Bulk_ESS	Tail_ESS
bwt_Intercept	7.49	0.16	7.20	7.7	79 1.00	608	839
tarsus_Intercept	20.47	0.30	19.92	21.0	3 1.00	868	803

Further Distributional Parameters:

	Estimate	Est.Error	1-95% CI	u-95% CI	Rhat	Bulk_ESS	Tail_ESS
sigma_bwt	1.97	0.16	1.66	2.28	1.06	27	172
sigma_tarsus	4.24	0.30	3.63	4.82	1.04	72	162

Residual Correlations:

Estimate Est.Error 1-95% CI u-95% CI Rhat Bulk_ESS Tail_ESS rescor(bwt,tarsus) 0.39 0.09 0.21 0.55 1.02 95 179

Draws were sampled using sampling(NUTS). For each parameter, Bulk_ESS and Tail_ESS are effective sample size measures, and Rhat is the potential scale reduction factor on split chains (at convergence, Rhat = 1).

plot(brms_m2.1, ask = FALSE)

It is also possible to extract the correlation. Just to remember it is an example, the correlation distribution is skewed to 1 due to a weak prior and model parameters. Note, since

```
cor_g <- as.mcmc((VarCorr(brms_m2.1, summary = FALSE)$animal$cor[, 1, 2]))
cor_res <- as.mcmc((VarCorr(brms_m2.1, summary = FALSE)$residual$cor[, 1, 2]))

Here we can plot the genetic correlation by extraction the breeding values or BLUP.

```
bls_m2.1 <- ranef(brms_m2.1)$animal</pre>
bl_m2.1 <- as.data.frame(abind::abind(lapply(1:dim(bls_m2.1)[[3]], function(x) bls_m2.1[, c(1, 3,
colnames(bl_m2.1) <- paste0(rep(dimnames(bls_m2.1)[[3]], each = 3), c("", "_lo", "_up"))</pre>
bl_m2.1$id <- rownames(bl_m2.1)</pre>
```

Here, some simple code to plot the genetic correlation.

```
plot(tarsus_Intercept ~ bwt_Intercept, bl_m2.1,
  xlab = "", ylab = "",
 xlim = c(min(bl_m2.1$bwt_Intercept_lo), max(bl_m2.1$bwt_Intercept_up)),
 ylim = c(min(bl_m2.1$tarsus_Intercept_lo), max(bl_m2.1$tarsus_Intercept_up)),
  las = 1.2, type = "n"
with(
  bl_m2.1,
  segments(
   x0 = bwt_Intercept, y0 = tarsus_Intercept_lo,
   x1 = bwt_Intercept, y1 = tarsus_Intercept_up,
    col = "black"
  )
```

```
with(bl_m2.1, segments(
    x0 = bwt_Intercept_lo, y0 = tarsus_Intercept,
    x1 = bwt_Intercept_up, y1 = tarsus_Intercept,
    col = "black"
))
points(tarsus_Intercept ~ bwt_Intercept, bl_m2.1, pch = 16, col = "red", cex = 1.5)
points(tarsus_Intercept ~ bwt_Intercept, bl_m2.1, pch = 1, col = rgb(0, 0, 0, 0.3), cex = c(1.5))
mtext("btw (BV±CI)", side = 1, line = 2.4)
mtext("tarsus (BV±CI)", side = 2, line = 2, las = 3)
```

7.0.2. Adding fixed and random effects

Fixed and random effects can be added just as for the univariate case. Given that our full model of bwt from tutorial 1 had sex as a fixed effect as well as random effects of byear and mother, we could specify a bivariate formulation of this using the following code (including a line to save the output):

```
bf_bwt_2 <- bf(bwt ~ 1 + sex + (1 | a | gr(animal, cov = Amat)) + (1 | b | byear) + (1 | c | moth
bf_tarsus_2 <- bf(tarsus ~ 1 + sex + (1 | a | gr(animal, cov = Amat)) + (1 | b | byear) + (1 | c

brms_m2.2 <- brm(
bf_bwt_2 + bf_tarsus_2 + set_rescor(TRUE),
data = gryphon,
data2 = list(Amat = Amat),
chains = 2, cores = 2, iter = 1000</pre>
```

```
save(brms_m2.2, file = "data/brms_m2_2.rda")
Again we have provided the data from one such run. It can be accessed using the code:
load("data/brms_m2_2.rda")
summary(brms_m2.2)
Warning: Parts of the model have not converged (some Rhats are > 1.05). Be
careful when analysing the results! We recommend running more iterations and/or
setting stronger priors.
Warning: There were 4 divergent transitions after warmup. Increasing
adapt_delta above 0.8 may help. See
http://mc-stan.org/misc/warnings.html#divergent-transitions-after-warmup

7.0.3. Partitioning (co)variances

As in the tutorial 1, it is possible to partition the variance-covariance matrix between groups (here sex)

```
bf_bwt_3 <- bf(bwt ~ 1 + sex + ((1 | a | gr(animal, cov = Amat, by = sex))) + (1 | b | byear) + (
bf_tarsus_3 <- bf(tarsus ~ 1 + sex + (1 | a | gr(animal, cov = Amat, by = sex)) + (1 | b | byear)

brms_m2.3 <- brm(
    bf_bwt_3 + bf_tarsus_3 + set_rescor(TRUE),
    data = gryphon,
    data2 = list(Amat = Amat),
    chains = 2, cores = 2, iter = 1000
)

save(brms_m2.3, file = "data/brms_m2_3.rda")</pre>
```

Again we have provided the data from one such run. It can be accessed using the code:

```
load("data/brms_m2_3.rda")
summary(brms_m2.3)
```

Warning: Parts of the model have not converged (some Rhats are > 1.05). Be careful when analysing the results! We recommend running more iterations and/or

setting stronger priors.

Warning: There were 6 divergent transitions after warmup. Increasing adapt_delta above 0.8 may help. See http://mc-stan.org/misc/warnings.html#divergent-transitions-after-warmup

```

However, this model is lacking an important and essential group-specific partitionning (we do with the asreml-R and MCMCglmm). We need to partition the residual variance (or sigma) as well. Doing so, we will use the argument 'sigma" to partition the model by sex. To avoid an estimation of the difference between sexes, we need to remove the estimate of the intercept at the sigma level.

```

7.0.4. Between groups (co)variances and the B-matrix

Animal models are amazing model. With different group within a population, it is also possible to estimate how much the different groups shared the same genetic via the cross-group genetic covariance. This covariance is essential to understand ontogenic or sexual conflict, which can constraint or enhanced response to evolution. As an example, we estimate the cross-sex genetic correlation r_{fm}

It is important to keep in mind the covariance matrix at the residual level is zero and it is important to avoid estimating the cross-sex residual covariance because no individual switched sex during the experiment.

Note: the way of partitionning variance per sex is a bit different then the previous code ",by=sex".

This code is faster and also easier to understand. Note, it is possible to play with the | or | | to estimate or not covariance between sexes.

```
bf_bwt_5 <- bf(
  bwt ~ 1 + sex + (0 + sex | a | gr(animal, cov = Amat)) + (0 + sex | b | mother) + (0 + sex | c
  sigma ~ sex - 1</pre>
```

```
bf_tarsus_5 <- bf(
    tarsus ~ 1 + sex + (0 + sex | a | gr(animal, cov = Amat)) + (0 + sex | b | mother) + (0 + sex |
    sigma ~ sex - 1
)

brms_m2.5 <- brm(
    bf_bwt_5 + bf_tarsus_5 + set_rescor(TRUE),
    data = gryphon,
    data2 = list(Amat = Amat),
    chains = 2, cores = 2, iter = 1000
)
save(brms_m2.5, file = "data/brms_m2_5.rda")</pre>
```

Again we have provided the data from one such run. It can be accessed using the code:

```
load("data/brms_m2_5.rda")
summary(brms_m2.5)
```

Warning: Parts of the model have not converged (some Rhats are > 1.05). Be careful when analysing the results! We recommend running more iterations and/or setting stronger priors.

Warning: There were 45 divergent transitions after warmup. Increasing adapt_delta above 0.8 may help. See http://mc-stan.org/misc/warnings.html#divergent-transitions-after-warmup

```
Family: MV(gaussian, gaussian)
Links: mu = identity; sigma = log
    mu = identity; sigma = log

Formula: bwt ~ 1 + sex + (0 + sex | a | gr(animal, cov = Amat)) + (0 + sex | b | mother) + (0 + sex | sigma ~ sex - 1
    tarsus ~ 1 + sex + (0 + sex | a | gr(animal, cov = Amat)) + (0 + sex | b | mother) + (0 sigma ~ sex - 1
```

Data: gryphon (Number of observations: 683)

Draws: 2 chains, each with iter = 1000; warmup = 500; thin = 1;

total post-warmup draws = 1000

The cross-sex genetic correlation can estimate form the output of the model. For tarsus length at fledging, sexes shared a lot of genetic variance which is commun for a trait with low sexual dimorphism. If the selection is antagonistic between males and females, sexes can not evolve freely from the other sexes and a intralocus sexual conflict can appeared.

with(bl_m2.5, segments(x0 = bwt_sex1_lo, y0 = bwt_sex2, x1 = bwt_sex1_up, y1 = bwt_sex2, col = "bwt_sex1_up, y1 = bwt_sex2, col = "bwt_sex1_up, y2 = bwt_sex1_up, y3 = bwt_sex1_up, y4 = bwt_sex1_up
points(bwt_sex2 ~ bwt_sex1, bl_m2.5, pch = 16, col = "red", cex = 1.5)
points(bwt_sex2 ~ bwt_sex1, bl_m2.5, pch = 1, col = rgb(0, 0, 0, 0.3), cex = c(1.5))
mtext("bwt male (BV±CI)", side = 1, line = 2.4)
mtext("bwt female (BV±CI)", side = 2, line = 2, las = 3)
plot(tarsus_sex2 ~ tarsus_sex1, bl_m2.5,
       xlab = "", ylab = "", las = 1.2, type = "n",
       xlim = c(min(bl_m2.5$tarsus_sex1_lo), max(bl_m2.5$tarsus_sex1_up)),
       ylim = c(min(bl m2.5$tarsus sex2 lo), max(bl m2.5$tarsus sex2 up))
with(bl_m2.5, segments(x0 = tarsus_sex1, y0 = tarsus_sex2_lo, x1 = tarsus_sex1, y1 = tarsus_sex2_
with (bl_m2.5, segments(x0 = tarsus_sex1_lo, y0 = tarsus_sex2, x1 = tarsus_sex1_up, y1 = tarsus_sex1_sex1_up, y1 = tarsus_sex1_up, y1
points(tarsus_sex2 ~ tarsus_sex1, bl_m2.5, pch = 16, col = "red", cex = 1.5)
points(tarsus_sex2 ~ tarsus_sex1, bl_m2.5, pch = 1, col = rgb(0, 0, 0, 0.3), cex = c(1.5))
mtext("tarsus male (BV±CI)", side = 1, line = 2.4)
mtext("tarsus female (BV±CI)", side = 2, line = 2, las = 3)
```

Within this model, we also have acces to the rest of the B-matrix. Note, the cross-sex genetic correlation is just the diagonal of the B matrix. For now on, you can explore this matrix and estimate the cross-sex-cross-trait genetic correlation.

Part III.

A repeated measures animal model

This tutorial will demonstrate how to run a univariate animal model for a trait with repeated observations using different R packages with an example data files provided.

Scenario and data

scenario

Since gryphons are iteroparous, multiple observations of reproductive traits are available for some individuals. Here we have repeated measures of lay date (measured in days after January 1) for individual females varying in age from 2 (age of sexual maturation) up until age 6. Not all females lay every year so the number of observations per female is variable (between 1 to 5). We want to know how repeatable the trait is, and (assuming it is repeatable) how heritable it is.

Data files

The pedigree file gryphonped.csv is that used in the preceding tutorials but we now use a new data file gryphonRM.csv. Columns correspond to individual identity (animal), birth year (byear), age in years (age), year of measurement (year) and lay date (laydate). Each row of the data file corresponds to a single phenotypic observation. Here the data is sorted by identity and then age so that the repeated observations on individuals are apparent. However this is not a requirement for analysis - data could equally be sorted by some other variable (e.g., measurement year) or be in a random order.

str(gryphonRM)

```

Asreml-R

library(asreml)

First we need to load the asreml library:

```
Loading required package: Matrix

Online License checked out Fri Apr 5 16:55:48 2024

Loading ASReml-R version 4.2
```

8.0.1. Estimating repeatability

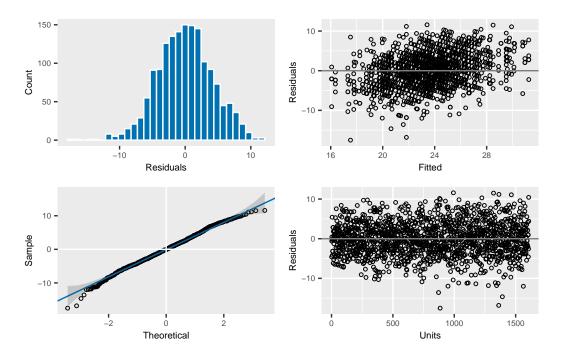

With repeated measures on individuals it is often of interest to see how repeatable a trait is. We can estimate the repeatability of a trait as the proportion of phenotypic variance V_P explained by individual variance V_{ind} ; $R = V_{ind}/V_P = V_{ind}/(V_{ind} + V_R).$

```
modelv <- asreml(
  fixed = laydate ~ 1,
  random = ~animal,
  residual = ~ idv(units),
  data = gryphonRM,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

ASReml Version 4.2 05/04/2024 16:55:48

	LogLik	Sigma2	DF	wall
1	-10182.83	1.0	1606	16:55:48
2	-8266.097	1.0	1606	16:55:48
3	-6145.012	1.0	1606	16:55:48
4	-4651.572	1.0	1606	16:55:48

10	-3497.536	1.0	1606	16:55:48

plot(modelv)

The model assumption seems correct, so we can look at the different estimates. Note that since we want to estimate the amount of variance explained by individual identity (rather than by additive genetic effects), we fit animal as a normal random effect and we don't associate it with the pedigree. Here, we also ask the model to remove any NA in laydate.

This model partitions the phenotypic variance in laydate as follows:

summary(modelv)\$varcomp

```
component std.error z.ratio bound %ch animal 11.08634 1.1794319 9.399728 P 0 units!units 21.29643 0.8896196 23.938798 P 0 units!R 1.00000 NA NA F 0
```

Between-individual (or among-individual) variance is given by the animal component, while the residual component (units!units) represents within-individual variance. Here then the repeatability of the trait can be determined by hand as 0.34 (*i.e.*, as 11.086/(11.086 + 21.296)).

Mean lay date might change with age, so we could ask what the repeatability of lay date is after conditioning on age. This would be done by adding age into the model as a fixed effect.

```
modelw <- asreml(
  fixed = laydate ~ age,
  random = ~animal,
  residual = ~ idv(units),
  data = gryphonRM,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

ASReml Version 4.2 05/04/2024 16:55:50

```

The repeatability of lay date, after accounting for age effects, is now estimated as 0.43 (i.e., as 12.29/(12.29 + 16.38)). So, just as we saw when estimating h^2 in Tutorial 1, the inclusion of fixed effects will alter the estimated effect size if we determine total phenotypic variance as the sum of the variance components. Thus, proper interpretation is vital.

```

Here age is modeled as a 5-level factor (specified using the function as.factor() at the beginning of the analysis). We could equally have fitted it as a continuous variable, in which case, given potential for a late life decline, we would probably also include a quadratic term. In addition, using age as continuous variable can help in saving some degree of freedom in the analysis.

8.0.2. Partitioning additive and permanent environment effects

Generally we expect that the repeatability will set the upper limit for heritability since among individual variation can be decomposed in the additive genetic variation and non additive genetic variation. In other word, the additive genetic variation is a subcomponent of the difference between individuals. Non-additive contributions to fixed among-individual differences are normally referred to as $permanent\ environment\ effects$. If a trait has repeated measures then it is necessary to model permanent environment effects in an animal model to prevent upward bias in V_A .

To illustrate it, we first fit the animal model:

```
gryphonped <- read.csv("data/gryphonped.csv")
gryphonped$id <- as.factor(gryphonped$id)
gryphonped$father <- as.factor(gryphonped$father)
gryphonped$mother <- as.factor(gryphonped$mother)

ainv <- ainverse(gryphonped)

modelx <- asreml(
    fixed = laydate ~ age,
    random = ~ vm(animal, ainv),
    residual = ~ idv(units),
    data = gryphonRM,
    na.action = na.method(x = "omit", y = "omit")
)</pre>
```

ASReml Version 4.2 05/04/2024 16:55:50

	LogLik	Sigma2	DF	wall
1	-8751.390	1.0	1602	16:55:50
2	-7169.205	1.0	1602	16:55:50
3	-5427.604	1.0	1602	16:55:50
4	-4219.598	1.0	1602	16:55:50
5	-3569.815	1.0	1602	16:55:50
6	-3382.341	1.0	1602	16:55:50
7	-3352.867	1.0	1602	16:55:50

```
8 -3351.565 1.0 1602 16:55:50
9 -3351.560 1.0 1602 16:55:50
```

Variance components are almost unchanged if we compare the previous model:

```
summary(modelx)$varcomp
```

```
component std.error z.ratio bound %ch vm(animal, ainv) 13.91784 1.443968 9.638607 P 0 units!units 16.84008 0.707365 23.806768 P 0 units!R 1.00000 NA NA F 0
```

summary(modelw)\$varcomp

```
component std.error z.ratio bound %ch animal 12.28982 1.156115 10.63027 P 0 units!units 16.37989 0.686619 23.85586 P 0 units!R 1.00000 NA NA F 0
```

This suggests that most of the among-individual variance is — rightly or wrongly — being partitioned as V_A here. To instead to obtain an unbiased estimate of V_A , we need to partition for both additive genetic *and* non-genetic sources of individual variation. We do it by fitting animal twice, once with a pedigree, and once without a pedigree (using ide()). Here, the command ide allow to create a second effect using a similar variable.

```
modely <- asreml(
  fixed = laydate ~ age,
  random = ~ vm(animal, ainv) + ide(animal),
  residual = ~ idv(units),
  data = gryphonRM,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

```

                                                    F
                                            NA
                                                        0
```

The estimate of V_A is now much lower since the additive and permanent environment effects are being properly separated. We can estimate h^2 and the repeatability from this model:

```
vpredict(modely, h2 ~ V1 / (V1 + V2 + V3))
```

Estimate SE h2 0.1701523 0.06073974

```
vpredict(modely, repeatability ~ (V1 + V2) / (V1 + V2 + V3))
```

Estimate SE

repeatability 0.4284108 0.02741602

8.0.3. Adding additional effects and testing significance

Models of repeated measures can be extended to include other fixed or random effects. For example try including year of measurement (year) and birth year (byear) as random effects.

```
modelz <- asreml(
  fixed = laydate ~ age,
  random = ~ vm(animal, ainv) + ide(animal) +
    year + byear,
  residual = ~ idv(units),
  data = gryphonRM,
  na.action = na.method(x = "omit", y = "omit")
)</pre>
```

Chapter 9

MCMCglmm

9.0.1. Estimating repeatability

With repeated measures on individuals it is often of interest to see how repeatable a trait is. We can estimate the repeatability of a trait as the proportion of phenotypic variance V_P explained by individual variance V_{ind} ; $R = V_{ind}/V_P = V_{ind}/(V_{ind} + V_R)$. As you already know, bayesian modelisation requires prior. Here, we create a unformative prior with one estimate for the G matrix and one estimate for the Residual matrix, in addition

```
# p.var <- var(gryphonRM$laydate, na.rm = TRUE)
prior3.1 <- list(G = list(G1 = list(V = 1, nu = 0.002)), R = list(
    V = 1,
    nu = 0.002
))
model3.1 <- MCMCglmm(laydate ~ 1,
    random = ~animal, data = gryphonRM,
    prior = prior3.1, verbose = FALSE
)
posterior.mode(model3.1$VCV)</pre>
```

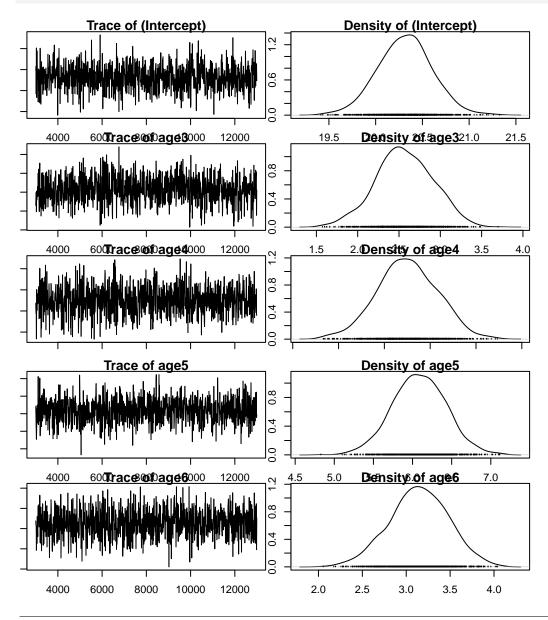

```
animal units 10.86091 20.82944
```

Note the use of the term animal as random allowed to partition the phenotypic variance V_P into among individual variance V_{ind} associated with animal and residual variance V_R associated with units.

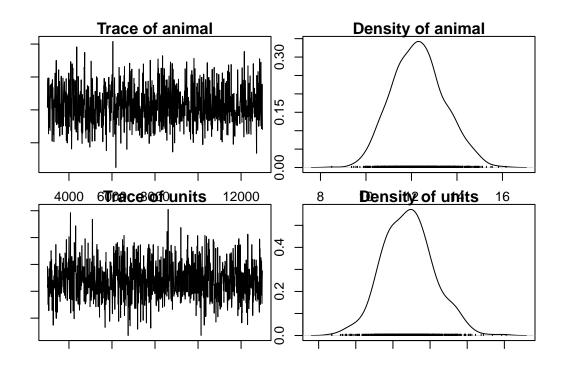

Here then the repeatability of the laydate can be determined as: 21.83 (*i.e.*, as 10.861/(10.861 + 20.829)). Just a friendly remember, we work with Monte Carlo chain with model iteration, so the point estimate can be different (but very similar) each time you run the model.

Mean lay date might change with age, so we could ask what the repeatability of lay date is after conditioning on age. This would be done by adding age into the model as a fixed effect.

```
model3.2 <- MCMCglmm(laydate ~ age,
    random = ~animal, data = gryphonRM,
    prior = prior3.1, verbose = FALSE
)
par(mar = c(1, 1, 1, 1))
plot(model3.2$Sol)</pre>
```

plot(model3.2\$VCV)

posterior.mode(model3.2\$VCV)

animal units 12.38103 16.63882

The model assumption seems correct, so we can look at the different estimates. Note that the random effect structure has remained unchanged because we did not modified the prior prior3.1. The repeatability of laydate, after accounting for age effects, is now estimated as 21.83 (i.e., as 10.861/(10.861 + 20.829)). Just as we saw when estimating h_2 in tutorial 1, the inclusion of fixed effects will alter the estimated effect size if we determine total phenotypic variance as the sum of the variance components. Thus, proper interpretation is vital.

posterior.mode(model3.2\$Sol)

(Intercept) age3 age4 age5 age6 20.425464 2.523479 4.086730 6.014407 3.064032

HPDinterval (model3.2\$Sol, 0.95)

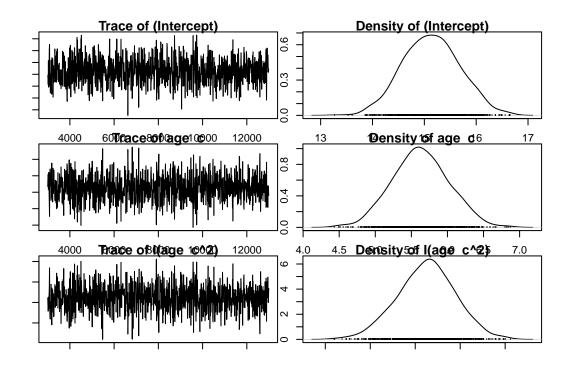

```
lower upper (Intercept) 19.766657 20.909736 age3 1.858847 3.207514 age4 3.666712 4.936830 age5 5.401191 6.734281 age6 2.500033 3.817123 attr(,"Probability") [1] 0.95
```

Here age is modeled as a 5-level factor (specified using the function as.factor() at the beginning of the analysis). We could equally have fitted it as a continuous variable, in which case, given potential for a late life decline, we would probably also include a quadratic term. In addition, using age as continuous variable can help in saving some degree of freedom in the analysis.

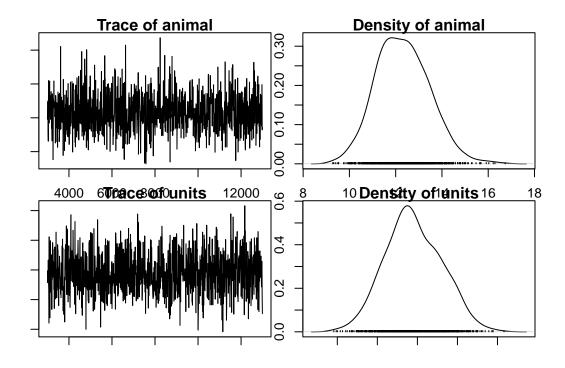

```
gryphonRM$age_c <- as.numeric(gryphonRM$age)

model3.2_2 <- MCMCglmm(laydate ~ age_c + I(age_c^2),
    random = ~animal, data = gryphonRM,
    prior = prior3.1, verbose = FALSE
)

par(mar = c(1, 1, 1, 1))
plot(model3.2_2$Sol)</pre>
```

plot(model3.2_2\$VCV)

[1] 0.95
```

9.0.2. Partitioning additive and permanent environment effects

Generally we expect that the repeatability will set the upper limit for heritability since among individual variation can be decomposed in the additive genetic variation and non additive genetic variation. In other word, the additive genetic variation is a subcomponent of the difference between individuals. Non-additive contributions to fixed among-individual differences are normally referred to as $permanent\ environment\ effects$. If a trait has repeated measures then it is necessary to model permanent environment effects in an animal model to prevent upward bias in V_A .

To illustrate it, we first fit the animal model:

```
Ainv <- inverseA(gryphonped)$Ainv
model3.3 <- MCMCglmm(laydate ~ 1 + age,
    random = ~animal, ginv = list(animal = Ainv),
    data = gryphonRM, prior = prior3.1, verbose = FALSE
)</pre>
```

Variance components are almost unchanged if we compare the previous model:

```
posterior.mode(model3.3$VCV)
```

```
animal units 14.21930 16.72339
```

```
posterior.mode(model3.2$VCV)
```

```
animal units 12.38103 16.63882
```

This suggests that most of the among-individual variance is — rightly or wrongly — being partitioned as V_A here. In fact here the partition is wrong since the simulation included both additive genetic effects and additional fixed heterogeneity that was not associated with the pedigree structure (i.e. permanent environment effects). In order to o obtain an unbiased estimate of V_A , we need to fit the individual identity twice in the model: once linked to the pedigree (genetic effect) and once not linked to the pedigree (permanent environment effect). To do so, we need to duplicate the variable containing the individual identity animal and give it a new name. In addition, the prior need to be modified to integrate a seconf random effect. An more appropriate estimate of V_A is given by the model:

```
gryphonRM$animal_pe <- gryphonRM$animal
# p.var <- var(gryphonRM$laydate, na.rm = TRUE)
prior3.4 <- list(G = list(G1 = list(V = 1, nu = 0.002), G2 = list(
    V = 1,
    nu = 0.002
)), R = list(V = 1, nu = 0.002))
model3.4 <- MCMCglmm(laydate ~ 1 + age,
    random = ~ animal + animal_pe,
    ginv = list(animal = Ainv), data = gryphonRM, prior = prior3.4, verbose = FALSE
)
posterior.mode(model3.4$VCV)</pre>
```

```
animal animal_pe units
4.504127 6.581995 16.422088
```

The estimate of V_A is now much lower (reduced from 13.6735 to 5.1238) due to a proper separation in the additive and permanent environment effects. We can estimate h^2 and the repeatability from this model:

```
model3.4.VP <- model3.4$VCV[, "animal"] + model3.4$VCV[, "animal_pe"] + model3.4$VCV[, "units"]
model3.4.PE_VA <- model3.4$VCV[, "animal"] + model3.4$VCV[, "animal_pe"]

posterior.mode(model3.4.PE_VA / model3.4.VP)

    var1

0.4305051

var1

0.1967684</pre>
```

9.0.3. Adding additional effects and testing significance

Models of repeated measures can be extended to include other fixed or random effects. For example we can try including year of measurement (year) and birth year (byear) as other random effects.

```
# p.var <- var(gryphonRM$laydate, na.rm = TRUE)
prior3.5 <- list(G = list(G1 = list(V = 1, nu = 0.002), G2 = list(
    V = 1,
    nu = 0.002
), G3 = list(V = 1, nu = 0.002), G4 = list(
    V = 1,
    nu = 0.002
)), R = list(V = 1, nu = 0.002))

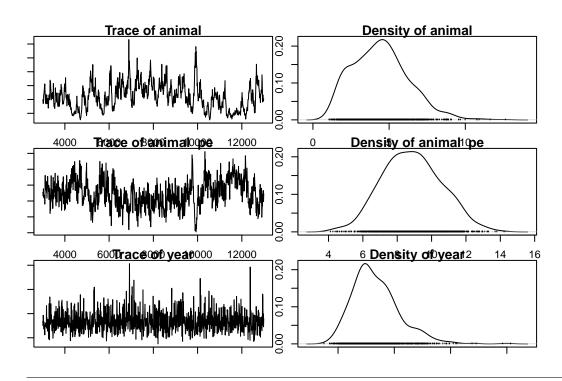

model3.5 <- MCMCglmm(laydate ~ 1 + age,
    random = ~ animal + animal_pe +
    year + byear, ginv = list(animal = Ainv), data = gryphonRM, prior = prior3.5,
    verbose = FALSE
)

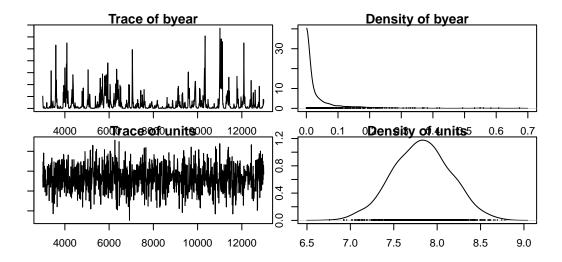

posterior.mode(model3.5$VCV)</pre>
```

animal animal_pe year byear units 4.960082394 7.637505328 7.307627958 0.002001744 7.821547902

HPDinterval(model3.5\$VCV, 0.95)

lower upper animal 1.2544168143 7.6547980 animal_pe 5.7268400934 12.1550360 year 4.8828176439 12.7172752 byear 0.0002349702 0.2001085 units 7.1394768368 8.4350045 attr(,"Probability") [1] 0.95

This model will return additional variance components corresponding to year of measurement effects and birth year of the female effects.

 V_{byear} is very low and its posterior distribution (via the function HPDinterval or plot) is very close to zero indicating its not significance. You have to remember bayesian model never estimate variable to 0 or passing zero, so you will never see a credible interval CI crossing zero for a variance. If you compared the DIC of model3.5 to a reduced model without byear, it should be very similar.

```
prior3.5_2 <- list(
    G = list(G1 = list(V = 1, nu = 0.002), G2 = list(
    V = 1,
        nu = 0.002
), G3 = list(V = 1, nu = 0.002)),
    R = list(V = 1, nu = 0.002)
)

model3.5_2 <- MCMCglmm(laydate ~ 1 + age,
    random = ~ animal + animal_pe +
        year, ginv = list(animal = Ainv), data = gryphonRM, prior = prior3.5_2,
    verbose = FALSE
)

posterior.mode(model3.5_2$VCV)</pre>
```

```
animal animal_pe year units 5.062924 7.750364 6.155458 7.648534
```

model3.5\$DIC

[1] 8290.236

model3.5_2\$DIC

[1] 8290.503

year effects could alternatively be included as fixed effects (try it!, you should be able to handle the new prior specification at this point). This will reduce V_R and increase the estimates of heritability and repeatability, which must now be interpreted as proportions of phenotypic variance after conditioning on both age and year of measurement effects.

brms

```
library(brms)

Amat <- as.matrix(nadiv::makeA(gryphonped))
gryphonRM$animal_pe <- gryphonRM$animal

model_simple1.1 <- brm(
    laydate ~ 1 + (1 | gr(animal, cov = Amat)) + (1 | animal_pe),
    data = gryphonRM,
    family = gaussian(),
    data2 = list(Amat = Amat),
    chains = 2, cores = 2, iter = 1000
)

summary(model_simple1.1)
plot(model_simple1.1)</pre>
```
